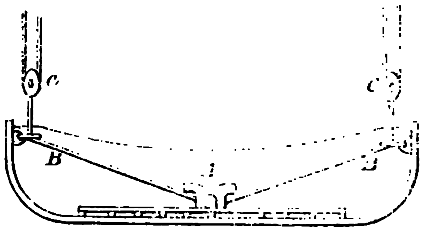
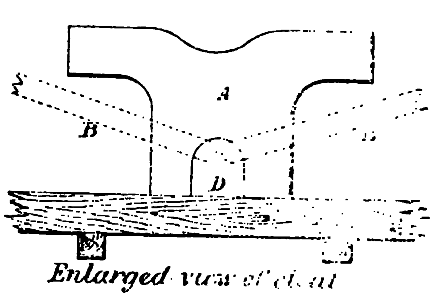
[22224.]—THE object of the boat-detaching contrivance about to be described is to provide a simpler and less expensive one than any now in use—one which is next to impossible to put out of order, not liable to be bent, rusted, frozen, or choked with dirt; it will even bear to be jumped on by a heavy seaman in his boots. It is certainly not self-acting, but the practised eye of an average seaman can be depended on to let go a rope at the right time.



Half section of boat



Enlarged view of cleat

It simply consists of a cleat A bolted in the middle of the boat to the kelson or bottom board in which a mast may be stepped. The cleat is made double legged where it is bolted down to the kelson, a hole D being made between the two legs, and is shown in larger size under the section of the boat. The tail ropes B B spliced or otherwise joined to the eyes of the blocks C C, through which the falls from the davits are rove, are continued through the rings of the ring bolts (to which the blocks are ordinarily hooked) and from thence brought, both of them, to the same side of the hole in the cleat, through which they are both passed. The two ropes are then slightly twisted round each other, and in their twisted state are passed sufficiently round the arms of the cleat to hold the weight of the boat. The free ends of the two twisted ropes, made as short as possible, are to be tied together with as weak a piece of twine as will hold them twisted, and may be hooked by the twine to any convenient place so as to keep the ropes constantly belayed. In this twisted state it will be easily seen that one end of the rope cannot be drawn out without the other.

When the boat is ready lowered for casting off, the sailor first slips the ends of the rope off the hook and holds them in his hand, either cutting the twine or not, it does not matter; at the proper moment he lets go the ends of the ropes, having, as every sailor knows how, just left enough turns of the ropes round the cleat to hold in his hand the weight of the boat. The twisted ropes run out at the same time as the boat falls instantly with the sea; if there is only a pull on one end of the boat, still both ropes run out and are freed at the same time. Either a few slats can be nailed up and down under the seats to confine the escaping ends of the ropes, or two short spouts may be made for the purpose.

The secret of the efficiency of the contrivance consists in just twisting the two ropes round each other sufficiently to make the one pull the other out with it, and at the same time to freely untwist themselves so as to offer the slightest hindrance to their separation.

31st Dec., 1883. **W. Byers.**

KEY CHARACTERISTICS IN MUSIC.

[22225.]—MR. TEMPLETON seems to be wandering away first on one side issue, then on another. I instanced the voice harmonium as a proof that there is no such thing as key characteristics when an instrument is in just intonation. Mr. Templeton demurred to that, because it seems he hurt his finger by a falling window, and, therefore, the voice harmonium "does not give perfect intonation" (p. 345). All I can say is, it ought to, and if it does not, it must be the fault of the tuner or the conjuring of the player. Mr. T., however, "knows" that when the reeds are set on end in the voice harmonium, the high-pitched ones "give no sound at all." Well, if that be so, there is an end to my contention, for, of course, it is impossible to say whether an instrument is in just intonation if it gives no sound at all, and also equally impossible to distinguish key characteristics—so, friend, I must be partly right after all. But allow me to hint just a doubt as to the soundness of Mr. T.'s knowledge. I suppose these speechless reeds were made to speak, and that they are willing to speak; why, then, don't they speak? Not because they happen to be placed on end, or because they are in the voice harmonium, or because they are tuned in true fifths—oh dear no! It is simply because the "master" was away, and Mr. T. does not know how to make them speak. Let him call in a reed voicer, and his reeds, high pitched or any other pitch, will speak fast enough. **N. E. Child.**

TRICYCLES.

[22226.]—IN fairness to my veracity, I hope our indulgent Editor will allow me to say a word or two in reply to our correspondent "Ex." (letter 22206), who seems to think that I complain without sufficient knowledge. I hope he will not be offended when I say that my remarks are based upon actual observation, and knowledge derived from having spent most of my life among machinery of all kinds, and a few of those years with an engineer's firm of very high repute. I have made out some hundreds of invoices of repairs, but I was never expected to condense them quite so much as "Ex." seems to do.

I am sorry that he seems to have even a lower estimation of some firms' commercial morality than I stated: but his remark about riders having no mechanical knowledge of what they buy would imply that their money is taken, and just any sort of machine work palmed on to them.

He says, with respect to cast iron being used, "good makers do not." I am afraid I could instance a good many parts about machines turned out by firms considered very good that are made of that material, and I have seen them broken and repaired, and in one or two instances I have had to get my own sliderest and tools at work.

I am speaking of machines made specially to order, and for which there was no haggling about base of the slide-rest, which would fit on to a set-square running between the shears on the top, or else fitting the head of bolt used for fixing hand-rest, and then when the work to be done was not longer than the traverse of the top slide, the rest might be shifted off the saddle on to top of bed, and thus save front slide from all unnecessary wear.

What would be the best way of working the nut? There would be very little room for the two halves to work upwards and downwards in. Is not a long half-nut used by some of the best makers now, instead of having the two halves to grasp the whole of the screw? **Fredk. Carre.**

COMPOUND ENGINES.

[22233.]—"ENGINEER, DEWSBURY," having candidly admitted that his engine could not work under the conditions he laid down in his first letter, and that I was correct in stating that there would be great danger of the high-pressure cylinder head giving way under the enormous pressure it would be exposed to from the compressed steam, your correspondent, "M. H. R.'s" suggestion, that a receiver be placed betwixt the two cylinders of ten times the capacity of the high pressure has assisted "Engineer" out of his dilemma to a certain extent. I should esteem it a great kindness if he would show what amount of power he would get out of his engine working under the amended conditions. "Engineer" states that my calculations are not correct as to the amount of power he would get out of his low-pressure cylinder. I stated that with 8½lb. average effective pressure he would get 37 h.p. I refer him to his formula as he gave it in his first letter, $\frac{14\cdot79 \times 360 \times 400}{33000} = 53\cdot8$ horse. If "Engineer" substitutes 8·5lb., which is the correct pressure, he will see that my figures are right. "Engineer" has also discovered that I am in error in stating the initial pressure in low pressure at 14·5lb.; he says it should be 14·4lb., an error of one-tenth of a lb. This is splitting hairs with a vengeance.

Dewsbury. **Engineer No. 2.**

CONCERNING LOCOMOTIVES.

[22234.]—MR. GREY, page 386, tells us that there seems much uncertainty as to the actual horse-power of locomotive engines, and confirms his perfectly correct statement by informing us that "persons likely to know" cannot give him the information. Here we have in a nut-shell the root of the question. It is this *uncertainty* with regard to horse-power which caused Pambour to look out for a better standard, and for this reason locomotive engineers express the power of their engines in *tractive force*, about which there is no uncertainty. *Theoretically*, the horse-power can be worked out in the way given by Mr. Grey; but, *practically*, the results will be useless, as the before-mentioned "*uncertainty*" exists. In short, it is to be regretted that the term *horse-power* was ever used with regard to locomotive engines.

Mr. Grey still appears to hold the opinion that the work an engine will do can be calculated from the dimensions; here I distinctly disagree with him. There are very many useful rules for calculating certain dimensions of parts, all of which are the result of actual experiment. A designer knows by experience the results of working of a certain class of engine. He considers that by making certain changes in design his next engine will give improved results. When the new engine is finished it is tested, and the nearer the practical working comes up to the expectations of the designer, the more it is in his favour. The idea that any fixed rule exists by which an engine can be designed and its actual working discovered, is, indeed, absurd: if only such a rule could be found we should require no more locomotive superintendents and designers, but only a person who could understand plain figures.

At the present moment many railway companies are making experiments with various designs of new engines or new parts, and to prove that experiments are necessary to success I can only say that, out of every twenty ideas (which look well on paper) when tried on the rails, not more than one proves successful. This opinion is the result of a long practical experience in locomotive engineering.

Manchester. **Historian, M.I.M.E.**

LIGHT AND HEAT.

[22235.]—IT has been stated that science knows nothing of the restorative energies of nature. However true this may be to the astronomer, or even the natural philosopher—although as students of the infinite, they might be credited with more exalted opinions of the powers of the human mind,—the examination of any portion of terrestrial matter reveals to the chemist there is concealed within it a form of energy whose power of expansion seems almost boundless. The various chemical compounds which on being exposed to heat or friction explode with varying rapidity and force, are examples of its action that cannot well be overlooked. And, although there are compounds so stable as to resist either for their decomposition, yet the existence of this expansive force within them is as undoubted as if it betrayed its presence by combustion or explosion. When the chemist endeavours to overcome the cohesion of these intractable substances, he accomplishes it by the addition of other elements of matter. Thus the action of aqua-regia on gold enables him to dissolve this most intractable substance, and a further addition of ammonia throws down a precipitate so unstable that the detonation of only a few grains is attended with tremendous energy. Now, he knows that the addition of nitrogen has not added to the amount of expansive force; there is the same quantity weight for weight in dynamite as in clay, and no more; but the power of cohesion to maintain the state of condensation in the dynamite is now nearly balanced by the presence of the condensed nitrogen, and the compound must be handled with caution. Precisely the same conditions are observed in all terrestrial substances. If a diamond is under examination he knows this piece of carbon, the hardest and most transparent of all solids, has nevertheless a hidden energy that would, if unopposed, expand it indefinitely. As the result of his analysis the chemist declares the existence in all terrestrial matter of two forms of energy, namely, a gravitating and condensing force, and a force of unlimited expansion; and, that in unvarying proportion, both are present in matter in all conditions, either solid, liquid, or gaseous. It remains for the astronomer to determine whether they exist in space dissociated from matter or not. Attraction of gravitation and the luminiferous ether pervade the universe; the question is whether matter in any form or condition is present with them.

An Inquiry into the Causes of Light and Heat.—The question "What is Light?" has been satisfactorily solved with the conviction that it must consist in the undulatory motion of an infinitely elastic substance pervading space. This was long considered the best explanation of the known phenomena of light, until it was finally proved a fact by Fresnel's interference experiment. The phenomena of polarisation demonstrate that the vibrations of light are at right angles to the direction of the rays, by showing that whereas in a ray of ordinary light the vibrations are transversal in all directions to the line of propagation; they are, when completely polarised, vibrating in one direction only. The phenomena attending refraction have also shown, by the difference in the rapidity of propagation of light in various refracting media, as well as the amount of deflection its rays suffer in their passage through them, that the density of the luminiferous ether varies in different substances; whilst the phenomenon of double refraction, as shown by various crystallised substances, notably Iceland spar, demonstrates this density to vary in different directions in the same substance. Thus the velocity of light in air as compared with water is as 4 : 3; whilst in glass it is as 3 : 2. Light is, therefore, propagated more slowly through strongly refracting than feebly refracting media, and formulates the law that the index of refraction between one medium and another is equal to the relation that the rapidity of propagation in the one medium bears to its rapidity in the other. The dispersion of light illustrates the remarkable fact that the luminiferous ether is not a simple but a compound substance, each component giving rays of different colours, different wave lengths, and different refrangibilities; so that in a colour dispersing medium the various kinds of light are propagated with different velocities and consequently differently refracted.

Having thus acquired a knowledge of the true nature of the luminiferous ether, that it is a substance infinitely expansible and elastic, pervading the entire universe, and contained in varying density by all natural substances, there remains for examination the cause of the vibrations called light.

The burning of magnesium in oxygen gives one of the most brilliant lights known, the product of combustion being the oxide of the metal. Now, the problem to be solved is the cause of the intense light. Before the solid metal can combine with the gas, it must itself assume the gaseous form. To enable it to do this it must be strongly heated to overcome the force of cohesion of its particles. This being effected, chemical affinity comes into play. The metal assumes the gaseous form, combines with the surrounding oxygen, and condenses into the solid white powder forming the product of the combustion. Observe the changes in the density of the materials and contained ether here described. First the solid metal expands into the gaseous form. This expansion is suddenly checked, and then, during or after chemical combination, as suddenly condenses into the solid form again. It is this sudden check to the expansion of the metal, followed by the condensation of both the chemically combined substances which produce the brilliant light. A powerful vibratory motion is effected in the condensing ether by the sudden stoppage of the expansion and the instant condensation, the intensity of the vibration and the consequent brilliancy of the light being in proportion to the extent and velocity of the condensation.

Thomas Ayers.

(*To be concluded.*)

REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[52132.]—**Excellent Yeast.**—I cannot discover in what particular "E. R. D." failed. If there does not come a scum on the liquid in making it, the yeast won't do. Be particular to have the flour dry. Perhaps here you failed. No matter how strong, it won't work well with damp flour. Try again with small quantities. There is no doubt the yeast is worth a few experiments.—BARLEY BREAD.

[52181.]—**Balance (?) Gear of Omnicycle.**—I find "W. H. S. W." is perfectly correct—the omnicycle has no balance-gear. It is a clutch driver. What is the advantage of the inside wheel only driving? Would some of your single-drivers tell us which is the easiest side to turn—viz., when the driving-wheel is on the inside or outside edge?—JOHN ALEX. OLLARD, Enfield.

[52205.]—**Chloroform Balsam.**—Care must be taken to get the chloroform absolutely pure; otherwise, the water in it will appear after a time, and cause spots. The same result can be obtained by breathing on the cover-glass or balsam just before mounting. I have mounted over 500 objects with chloroform balsam, and so long as the pure was obtained and used, the result was good. On one occasion, I used some slightly methylated, and the slides were spoilt. I understand that carbonate of potash will absorb all the water from the chloroform, thus leaving it absolute. In most cases, I think the balsam only hardened round the edges, thus leaving the object in a cell mounted in liquid balsam. I have slides mounted several years ago, where the chloroform balsam is still liquid in the centre, and there are no spots, &c.—JOHN ALEX. OLLARD, F.R.M.S., Enfield.

[52302.]—**The Cheapest Food.**—My reply to the remarks of "S. R.," on page 372, need not take up much space. This correspondent has said nothing which, in my opinion, shakes the simple statement made regarding Dr. Nichol's Food of Health and the American Breakfast Cereals, which are wholesome, delicious, and (on the whole under the circumstances) cheap. There are several points in "S. R.'s" communication on which I should like to touch, but will refrain, as the cheap food controversy raised by my friend appears to have concluded.—ARTHUR MEE.

[52307.]—**Gas Engine.**—Many thanks to "S. M." for his answer to my query. I will try and describe the faults of my engine. First, the engine is supposed to fire every revolution, but it don't; next, the charge is fired by the piston driving a small portion of the charge through a small hole, which is covered by a piece of wire-gauze. The said hole has a set-screw in it to regulate the quantity of gas that passes through into the hollow chamber in the valve, which is worked by an eccentric rod. The gas in the chamber coming in contact with the side-light, it is carried into the cylinder as a bead of fire, but with my engine it very often goes out, causing the charge to miss fire. There is not any air-pump, as in the Clerk engine, to wash out the products of combustion. Now, if I am not mistaken, after the explosion takes place it leaves the cylinder full of carbonic oxide, and not having a scavenger stroke the same as the Otto, the fresh charge of gas and air becomes mixed with the products of the last explosion, which I should think has a very detrimental effect to the proper combustion of the charge if it allows it to fire at all. I want to take away the present defective arrangement and put a slide in its place, so that it will have a scavenger stroke like the Otto, but I should like the slide to only have two faces, same as the Baron engine; I don't think they are so likely to cut up when they have two faces instead of four. If some reader will inform me the best way to start on the job I am certain I can carry it out successfully; I have a good lathe and plenty of tools at my command. I shall put a 4in. cogwheel on the shaft to drive the slide by a crank on an 8in. wheel, so that the slide will move once to every two revolutions of engine.—VOLT.

[52335.]—**Lacquering Brasswork.**—"Old Subscriber" will not be able to do good work in coppering bronzework without the battery. The best black bronzes are produced by the salts of platinum—the chloride, for instance. Dilute solution should be used, and the article should be heated. Chloride of antimony, with a little hydrochloric acid, will also give a black. Use the best [illegible] the stock, and colour to suit with dragon's blood, gamboge, [illegible], turmeric, red sandal and saffron. There should be [illegible] ready dissolved in [illegible], and by adding a little of one or the other, a mixture of two or more to the stock [illegible], you produce the [illegible]—[illegible]

[illegible]—**Test for Cane Sugar.**—Is there any difference between the crystals of cane and beet sugar? [illegible] an infallible test [illegible] depend on the [illegible] difference [illegible]

[illegible]—**Holtz Machine.**—[illegible] knowledge [illegible] Another [illegible] his statements [illegible]

[illegible]

[illegible] weight of water [illegible] more effect- [illegible] which they are [illegible] endeavour, then, to [illegible] much water as pos- [illegible] "M. Bourne" that the [illegible] are unsuitable, [illegible] as they pass [illegible] I would suggest that [illegible] similar to that shown in [illegible] which would not wholly [illegible] had the [illegible] until it

vertical centre at the bottom. The shrouds or sides should project about an eighth of an inch beyond the lips of the buckets. The water should be allowed to flow at first very gently, the quantity being increased in proportion to the speed with which the wheel revolves. This, of course, can be regulated to a nicety with a tap, and if these suggestions are carried out "Melbourne" need not waste the drop of water ineffectively.—WESTLAND.

[illegible]—**Watch License.**—An inquiry addressed to the Inland Revenue Office, Somerset House would produce an authoritative answer to this query. It seems to me it turns on the meaning of the word "agent," because a tradesman might call himself the agent of the manufacturers, especially when, as is often the case, he holds his stock [illegible] the makers—that is, on sale or return.—[illegible]

[illegible]—**Discharge of Water.**—The question [illegible] pipe, with a head of 50ft.: [illegible] must be allowed for friction. From [illegible] taking the head divided by length of [illegible] the delivery would be about 10 gal- [illegible]—[illegible]

[illegible]—**Pump.**—[illegible] the information [illegible] if it were my case, [illegible] deep, and [illegible] with a [illegible] pipe to the well. You [illegible] as much as you wanted. [illegible] as fast as the inch pipe [illegible]

[illegible]—**Removing Varnish from Oak Panelling.**—[illegible] the scraper with hot [illegible] varnish for oak [illegible]—M. [illegible]

[illegible]—There is no reason why raised [illegible] be as applicable to the [illegible] "Patent Plate" [illegible] the bridge in renewing [illegible] the whole of the [illegible] itself might have [illegible]. For this reason it [illegible] mark the position of the bridge [illegible]

[illegible]—**Skin Disease.**—"Mechanic" is [illegible] it appears in any part of [illegible] twice a day [illegible] at breakfast [illegible] globules of [illegible] globules of Thyra—[illegible]

[illegible]—**Siemens Dynamo.**—[illegible] the arrangement [illegible] diagram, and in the one I [illegible] the principle clear, not

[illegible] actual arrangement. It [illegible] drum armature of 8 divisions, or 16 [illegible] of wire, of which the wires in which the current ascends are numbered 1—15, odd numbers, and the descending currents 2—16, even numbers. Each section of the wire winds round and round the drum across the axis as nearly as space permits, so as to fill up the whole circumference; but in the diagram the ends only are considered, as though each section were a single turn of wire. It will be seen that an ascending and descending wire are everywhere side by side exposed to the same action, and therefore having opposite currents generated in them. These constitute the two opposing circuits presented to the collecting brushes and uniting as one, as in all this class of machines. The armature segments are equal in number to the sections of the wire—viz., 8 marked *a*, *b*–*h*, in a direction opposite to that of rotation, shown by the arrows in the field-magnet poles N. S. As shown, the most active sections are 1—16 and 8—9, while 2 [illegible] 3 will be the next to occupy the central line. Wire 1, in which the current ascends, is connected to armature section *a*, at which its current is given up to the brush; it is then continued to 2, which is one-eighth of the circle in advance of 16 against the rotation, so as to be carried forward by the motion. Wire 2 then descends, and crosses the drum at the further end diametrically, rising as 3. Here the wire has a branch to commutator segment *b*, and is also continued to the next descending portion 4, and so on, working round the cylinder, the end of 15 being joined to *h* on the commutator, and to 16 wire. Thus the whole wire forms one complete and endless circuit, divided at each pair of opposite segments, as they reach the brushes, into two opposed halves uniting as one in action externally. The easiest mode of winding is to construct a wood cylinder on the iron, of the thickness of the intended coils, dividing it into as many segments as there are of wire—16 in this case. These may be attached to the iron by one or two screws, or by clamps at the ends, and fitted with clasps to mount the whole in a winding machine. Now, if the two opposite segments are removed, we have a bobbin in which one of the coils can be wound securely; then an adjoining pair can be removed and the winding continued, and so on to completion.—SIGMA.

[52134.]—**Gout.**—Continual use of Physalis alkekengi is injurious to the system; on using it continually the rheumatism might settle itself in the bladder, and would be far more painful than at its present juncture. Take internally at breakfast in the drink, five globules of Bet. *a*, at dinner, in the drink, five globules of Per, at supper, in the drink, five globules of Thymus.—ETHEROPATHY.

[52443.]—**Overworked Brain.**—Takes Thymus 5 globules in drink at breakfast, Sedum 5 globules in drink at dinner, Antiventeux in drink at supper.—ETHEROPATHY.

[52462.]—**Bourdons.**—In reply to "S. O." (in the "E. M." of 14th Dec., 1883). I believe he should find no difficulty if he makes the pipes to a small scale, and voices them lightly—that is, not to make them "roarers." At present I am adding an octave of Bourdons, 16ft. tone, to a 5-stop organ which I built last winter. The scale I have adopted is [illegible] by 4¾ for C C C, and the pipes are diminished in regular proportions, one-eighth of an inch each way, till C C comes to 4¼ by 3¼. They are all square-mouthed, with lips cut low. The C C C and C C C sharp stand over their own wind; but the remaining pipes are conveyed off by tubes of 1in. diameter. All the pipes stand upon a surface of 3ft. by 2ft. The pedal soundboard is only 23in. by [illegible]in., 7in high. Distance of bellows is 2ft. With the weight of the bellows frame itself I find that the wind is almost sufficient to produce a round and full tone.—A. EVANS, Bank, Llandudno.

[52465.]—**Belt Working off Pulley.**—I do not wish to take upon me to answer for "R. R. N."—he doubtless will do that for himself; but I agree with him. And as "Firer" appears, from his letter, to have been practising and found that, contrary to mechanical rule, a belt will run down-hill rather than up, perhaps he will, for the benefit of our readers, show in what way he has tested the question, and how he has drawn his conclusions.—WM. HOSKEN.

[52474.]—**Strain on Jib Chain.**—From his questions on page 392 it seems that "Radnor" has but little knowledge of mechanics. He should attend lectures, or get a friend to put him in the way of reading on the subject. The two answers refer to a crane which is not exactly the "derrick." In the derrick crane there are two chains at or near the line A, the burden and the jib chain, and P is approximately the sum of the strains on the two chains. As the strain throughout the burden chain is W, the strain on the pit chain is P – W.—J. S. C.

[52474.]—**Strains on Jib Chain.**—In the case suggested by "Radnor," the strains will be, on the jib chains 7 tons, and on the jib a little over [illegible] tons. "Radnor" will see, from "J. S. C.'s" method, that he is wrong in supposing the leverage to be unaltered. He can check the above as follows:—Let him measure the length of jib chain, length of jib, and height of mast. Then let T represent jib chain, P the mast, J the jib, and W the weight on burden chain. Then the tension on the jib chain = $\frac{T}{P}$ W, and the compression of the jib = $\frac{J}{P}$ W. Of course, if the chain pass along T, and down the mast to the chain barrel, it relieves the tie-bar of an amount of tension equal to that in the chain—namely, W divided by the number of falls in the overhanging part of the chain. If the chain pass along the jib, the compression will be increased by an amount equal to the tension of the chain.—J. S. B.

[52483.]—**Neuralgia.**—Dr. [illegible] Mattei says, "Rub the top of the head and back of the neck, and ears, twice a day with the electric balm; take internally Thymus, Bet. [illegible], Vulv. [illegible] globules in drink at meals."—ETHEROPATHY.

[52489.]—**Rain Gauge.**—Would the plan I adopt help "M.M.I.Sc.S."? My gauge is by Negretti and Zambra; model similar to that described by "F. R. A. S." I use an old iron paint can as receiver, placing on it the funnel, keeping the tube part and measuring rod under cover, pre-

[illegible] for as [illegible] have that you [illegible] are creditor for it [illegible] must go to the [illegible] the surveyor of taxes [illegible] state: or [illegible] say—say [illegible] will give you all [illegible] to enable you to do all [illegible] at a distance [illegible] telling them what [illegible] they will be at home, and [illegible] most easily with the help [illegible] experience of the matter.—[illegible]

[illegible] **St. Petersburg Standard.**—[illegible] are [illegible] sold at so much per [illegible] in their thickness [illegible] boards at so much per [illegible] Petersburg Standard. This standard is [illegible] long, 11in. wide, and [illegible] a matter of figures to [illegible] into this standard. The [illegible] is 2 standards, 1 [illegible] representing 26½ pieces of [illegible] at [illegible] each = £15 19s. 2d. —[illegible]

[illegible] **St. Petersburg Standard.**—In [illegible] Jno. Wilson, a Petersburg standard [illegible] deals consists of 120 pieces, [illegible] and contains 1,980 superficial feet. Any quantity or variety of scantlings are [illegible] by reducing them to [illegible] feet and dividing by 1,980 for hundreds, [illegible] quarters of hundreds, and [illegible] single-standard deals; the [illegible] performed by doubling the [illegible] fractions are generally [illegible]. There are many short methods; but your space cannot be further occupied.

[illegible] deals, at £14.
[illegible] 5 0 0
[illegible] 4 10 0
[illegible] 1 7 0
[illegible] 0 1 2
£11 18 2

[illegible] pounds, if doubled, gives [illegible] pence or of a dozen in [illegible] Dublin.

[illegible] **Thermometer Screens.** The querist will [illegible] information on p. 267, No. 948, [illegible] but dimensions in the fifth line from the bottom should read dimensions. It is not in my power to give any more detail, or I would with pleasure. [illegible]

[illegible] **Bunsen** [illegible] should use dry coils. [illegible] good results from their [illegible] likely because the tube [illegible] and the temperature of [illegible] and lay boiler [illegible] non-conducting com[illegible] pavement.

[illegible] **Rapid Break.** To Mr. P. Ward. [illegible] that there are [illegible] tube which no [illegible] current, will make [illegible] general rule my rapid [illegible] states. I usually [illegible] plates [illegible] battery connected in [illegible] spark is not [illegible] are got with an [illegible] two forms of my rapid [illegible] Proceedings of the Royal [illegible] The first is auto[illegible] by hand. The [illegible] 6,000 currents [illegible] second. The theory [illegible] more uniform current [illegible] primary of an induction [illegible] the tube has not [illegible]

[illegible] **Eyepieces.** Tolles' eye[illegible] Mechanic, [illegible] No. 124 its [illegible] are detailed. [illegible] by filling [illegible] F.R.A.S." [illegible] of grinding, says [illegible] "I have [illegible] all possible [illegible] in the future, [illegible] the use of one eye [illegible]

[illegible] of the rubber [illegible] pretty and in [illegible] at the exact [illegible] P. Ward.

[illegible] **Clarionet Fingering.** [illegible] key [illegible] with B natural, and [illegible] does not produce good [illegible] shakes are impossible by the ordinary fingering. 2. Yes, you may proceed as you suggest, and in that case the above key will be used for the shake or trill on G natural with A natural, and A flat with B flat: but remember that if ever you should wish to play music which is written for the B flat clarionet (in company with other instruments), you will then have to transpose. If you had a C clarionet you could play with the piano without transposing, and the fingering would be much easier.—OLD BLOW HARD.

[52620.]—**Pyrotechny.**—The French and German works on pyrotechny are useless for teaching modern pyrotechnics. The English works named by "J. M. B." are the latest that have been published, and give one a fair idea of what has been done. All the new and most scientific principles of working are secrets—the work of years—and consequently will not be made public. If expense is no consideration, and "J. M. B." wishes to have all the latest information, and will advertise his address in "ours," I will try to help him. The spiral wreath of smoke from the balloon, or rather from the light this carries, is caused by the rotation of the case containing the magnesium light.—SCRUTATOR.

[52623.]—**Mural Decoration**—I am afraid our querist "E. C. N." will give himself an amount of trouble if he intends to prepare his walls for what he purposes to do. If he has the back numbers of the "E. M." and will refer to the number for October 26, p. 177, and read the article "Preparing Millboards," which I need not now repeat, it will give him some idea of the preparation required. In the first instance, however, a slight alteration from the directions there laid down will be needed. Having cleared the paper from the walls, he will have to thoroughly saturate the plaster with boiled linseed-oil, and when dry, repeat it until the plaster will absorb no more: when that is dry, he must follow the directions as laid down for "millboards,"—coating with ceruse and rubbing down with pumicestone;—unless the plaster surface is very hard and solid, his labour will not be of the least use. Instead of oils, "E. C. N." might paint in distemper; in that case, very little preparation would be necessary; perhaps, none.—GEO. H. LANCASTER.

[52628.]—**Thought Reading by Machinery.**—My opinion is, that it would be absolutely impossible to affix wires to the glass plates in Mr. Maskelyne's thought reader. Even the finest silver (which is the best conductor of electricity) would be seen at a glance.—P. WARD.

[52628.]—**Thought Reading by Machinery.** I do not know what is the nature of the mechanism between the operator and the automaton "Zoe," which enables the latter to write down the *numbers* in thought reading, or to draw the outline of a person's face, as exhibited by Messrs. Maskelyne and Cooke. Apart from any electrical or ocular signals, it struck me, when I saw the figure write down the number of a bank note, that as Mr. Maskelyn stood facing the audience, with the note held face upwards in his hand, at some little distance from his body, it would be very easy for a confederate concealed in the ceiling or upper part of the stage, provided with an opera-glass or telescope, to read for himself the number of the note, and so communicate it to the person who manipulates "Zoe." A suspicious element, I may remark, in the thought reading attributed to occult power, is that it is almost exclusively confined to numbers, easily communicated by signal. Mr. Maskelyne is quicker and does more than the mystery-mongers.—EYE-WITNESS.

[52625.]—**Field Glass.**—In reply to "Burgee's" first question, Chambers says, in the Galilean telescope the distance between the glasses is the difference of their focal lengths, and the magnification the ratio of their focal lengths.—ARTHUR MEL.

[52630.]—**Muffins.**—Mix a quartern of fine flour with a quart of warm milk and water, 2oz. of salt, and a wineglassful or so of yeast; then add another quartern of flour, mix well, let it rise for an hour. Knock it up, pull into pieces the shape of balls about enough for a muffin. Keep in a warm place, and when all the dough is worked up, flatten the balls into muffins and bake on tins. Turn when half done. Some dip into warm milk at this stage, which helps to impart a pale brown colour.—B. M.

[52631.]—**Dynamo Machine.**—A machine made double the size in every way would give four times the current, and would take four times the power to drive to work it to the full. I should, therefore, not advise A. Ritchie to double the size of the dynamo, unless he is prepared to use a small steam-engine or gas-engine to drive it. The dimensions given in the "E. M." will produce a dynamo which will tax a strong man to keep going for even a quarter of an hour. If made exactly twice the size, it will require a half horse-power engine to work it, and should be constructed without the standard and driving wheel, but should be driven by means of a belt and rigger. The size of the wire to be used will depend on the nature of the current required. If the external resistance is small, use No. 16 silk-covered for both magnets and armature. Put about 7lb. on each leg, and about 1lb. on the armature. If the external resistance is greater you may use No. 22, silk-covered, for both magnets and armature. Finer wire than this is not advisable. Remember also, although I recommend the old H-pattern armature for small hand dynamos as being very effective, very easy to make, and not easily put out of order: yet it is one of the worst kinds for large dynamos, which have to be worked for any length of time, since it soon gets very hot, and the insulation breaks down through that cause after 20 or 25 minutes' continuous work.—S. BOTTONE.

[52632.]—**Gas Stoves.**—The "Lux-Calor" is one of the best "stoves" (without flue) in the market; but I should advise Mr. Harcourt to look at Mr. Fletcher's latest, for cheerfulness and efficiency. It has a flue, and can be set on any hearth, or near an opening into the outer air, in two minutes, and can be either connected by flexible tube to the nearest gas-jet, or specially connected to a pipe under the floor, if desired. It is the only *economical* imitation of a fire which I have seen. I think the price is 21s. It is said to consume only 7ft. per hour.—P. WARD.

[52632.]—**Gas Stoves.**—The combustion of either coal or gas results in the production of water and carbonic acid, and no stove can possibly be healthy for a bedroom that does not possess an outlet to the external air. If Mr. Harcourt wants to rig up something of a temporary kind, he will find instructions in back numbers; or he should get a look at a calorigen. If I wanted anything of the kind I should fit up one of Fletcher's little gas-stoves in such a manner that it would heat air coming in from the outside, while the only connection with the atmosphere of the room would be where the air was drawn in to supply the burner. In other words, the chimney would pass outside, and might very well be a tube passing through the centre of a larger one by which the fresh air could be brought into the room.—NUN. DOR.

[52633.]—**Gas Flames.**—I believe there is economy in blending two gas flames, the rationale being that the result insures the exact amount of heat to render the carbon atoms in a state of highest incandescence before their conversion into carbonic acid. The Bunsen flame is the reverse of this.—P. WARD.

[52634.]—**Fluorescence.**—The most perfect manner Mr. Harcourt can adopt for the illustration of fluorescence is to use a good white light, rich in ultra-violet, and condense it from an ordinary lantern, having put in his condenser-cell, or other suitable place, some very deep violet glass (or about five or six thicknesses of ordinary blue glass will do). His stramonium should be an alcoholic solution. Among other materials he will find a decoction of madder in a solution (aqueous) of alum gives very good results; uranium glass, and many of the aniline colours in alcohol, especially fluorescine and eosine. The explanation of the phenomenon is, that rays of high refrangibility are rendered less so by the substances on which they impinge. Glass absorbs these highly refrangible rays to a great extent, so that quartz is used (which only absorbs a very few of them) for constructing the condensers where the greatest nicety is required. The electric discharge in a carbonic acid vacuum is very rich in these rays. Indeed, the natural phenomenon of aurora borealis is accompanied by rays of this kind.—P. WARD.

[52636.]—**Dihedral Angle.**—Is the angular space included between two planes which meet each other.—R. P. G.

[52636.]—**Dihedral Angle.**—The angle between two planes is called a dihedral angle, and is the angle between two lines drawn, one in each plane, perpendicular to the line of intersection of the planes from any point in that line.—C. W. B.

[52636.]—**Dihedral Angle.**—By this term is meant the angle made by two planes which intersect. In the usual method of representing planes by traces, this angle is not shown, but can be determined by a simple construction.—WM. JOHN GREY, Elswick Science School.

[52636.]—**Dihedral Angle.**—(Greek *dis* twice, and *hedra*, a side or face—foundation or base), having two sides or surfaces. Dihedron (another word), a figure with two sides or surfaces. I have never met with these words in any work on geometry that I have seen.—GEO. H. LANCASTER.

[52636.]—**Dihedral Angle**.—If "Coachmaker" had consulted any large dictionary, he would have found that dihedral (from the Greek *dis* twice, and *hedra* a seat) means having two sides or surfaces. Hence, dihedral angle is the angular space between two planes which meet each other.—EYE-WITNESS.

[52639.]—**Netting.**—"Hammock" cannot do better than procure a little work called "Netting," [illegible] and filed a flat on [illegible] cutting wheel on I [illegible] wheel on, making all [illegible] I find that it has [illegible] crank to move without [illegible] as tight a fit as possible for [illegible] key it from the front, as the [illegible] the axle too far up—about [illegible]in.—[illegible]

[illegible]—**Bristol and Exeter Single Express.**—Will any kind correspondent give particulars of this [illegible] Is it a broad gauge one? Are any of them [illegible] Any information will greatly oblige.—[illegible]

[illegible]—**G.N. Engines.**—Can any correspondent give particulars of 7[illegible] class, mixed engine, with outside [illegible] turned out last year? Is this a rebuild, or a new type?—H. N.

[52665.]—**Water Blower.**—Will some of my fellow-readers oblige with the working drawings of a water blower suitable for forge in a workshop? I have tried to make one according to what I heard about it; but it won't work. I don't get enough wind to keep the fire alight. I have a good water supply, and I am quite anxious to have one of the above-mentioned blowers at work. Perhaps some of our numerous readers will assist me.—YOUNG ENGINEER.

[52666.]—**Peep Show.**—Will some one kindly say how to fit up the inside of a peep show? I have bought one 3ft. 6in. long, 2ft. wide, and 2ft. 6in. high, and want to improve it. It has seven peep holes, and only shows a few photographs now.—SHOWMAN.

[52667.]—**Soil Pipes.**—Will Mr. Davies, or any other reader, explain how double bends are turned on long lengths of soil pipes?—YOUNG PLUMBER.

[52668.]—**L.B. & S.C. Engines.**—Can any reader give me dimensions of Craven's double-framed engines on this line (1) four coupled pass. engines—e g., 176, 1[illegible], 147, 148, &c. (2) Single engines, 194—200 class. Also Horsham, Norwood, &c. How many are there of these classes? Also, how many engines are there of Grosvenor class? This is the only one I know with 6ft. 9in. wheels? I do not mean 6ft. 6in. engines (325—359 class).—METEOR.

[52669.] **L. C. & D. Engines.**—I have recently come across dimensions of some 5ft. 3in. double-framed goods engines, one of which is named Constantine. Can any reader say how many of these there are, with their nos.? Also, what were the nos. of the Sharp Stewart's goods, a class of which one was in Exhibition of 1862?—METEOR.

[52670.] **Continuous Temperature.**—Can any one show me how to make an apparatus to keep one drachm of liquid at 100° Fahr. for three days?—HEAT.

[52671.] **Derbyshire Lime.**—Will Mr. Grey kindly give me a rough average analysis of the above?—L. B[illegible].

[52672.] **Cleaning Gaiters.**—I wear drab Canton (or jean) gaiters, which in wet weather get spotted. Will any reader kindly tell me how to clean them, and remove the spots or patches? I have tried pipeclay, but it is useless for the purpose.—CORPORAL.

[52673.] **Children Sleeping with Aged Persons.**—I shall be glad to know if it is really unhealthy for a child (or young person) to sleep with one much older than themselves? Also if it is at all unhealthy to sleep with any one who is in ill health, or delicate?—J[illegible].

[52674.] **Photo. Etching.**—Can any reader give me some good practical method of etching on copper plates by the aid of photography?—F. H.

[52675.] **Clayton's Gas-Engine.**—Will some reader kindly inform me how Clayton's gas engines explode the gas? When the piston is at the proper position, they are exploded with a red hot tube every second revolution. How is it the gas is not ignited when the crank is on the centre, or even before? Is it because the gas will not reach the hot part of tube until the proper amount of pressure is on, then that would be when crank is on the centre?—T. A.

[52676.] **Printing Paperhangings.**—How are the colours mixed for this process, and how are they applied?—X. L. C. R.

[52677.] **Casting Lead.**—What can I mix with lead to make it run easily? If antimony, in what proportion, and how to amalgamate?—X. L. C. R.

[52678.] **Printing Inks.**—How made? What [illegible] kindly confer this information?—X. L. C. R.

[52679.] **Bread Adulteration.**—To MR. A. H. ALLEN.—Is the addition of cooked potato considered an adulteration, and how best detected? Also, is there [illegible] amount of water, as I recently came across [illegible] containing [illegible] per cent., when dried to [illegible] the [illegible] bread [illegible] the moisture, in fact my [illegible] after the operation. The [illegible] Are any salts used [illegible]—AMATEUR.

[52680.] **Copper Sulphocyanide.**—To MR. A. H. ALLEN.—[illegible] a solution of ammonium sulphocyanide [illegible] sulphate of copper a [illegible] changing to white [illegible] any sulphide with [illegible] nitrate of silver or sulphate of [illegible] potassium sulphocyanide to [illegible] copper sulphate, I fail to get any [illegible] will oblige.—AMATEUR.

[52681.] **Legal.**—Can any one say if a claim on [illegible] is a legal one? He [illegible] Charles the Second's [illegible] to keep the Royal [illegible] Is it not a fact [illegible] (if ever legal), were [illegible] This particular [illegible] in private hands, and is [illegible] who pay it consider it [illegible] and that if [illegible] the payment would [illegible] on certain livings [illegible] scattered here and there—Norfolk being, I believe, specially burdened.—J. LUKIN.

[52682.]—**Electrical Problem.**—Two selenoids, one 12 centimetres long, 3cm. diameter, and 48 turns, the other 15cm. long, 2cm. diameter, and 81 turns, are suspended with axes in same straight line at a distance of 20 centimetres, and a current ·95 was sent through both in opposite directions. Find the force with which they repel one another in dynes. Prove that we get the greatest deflection of a galvanometer needle when the resistance of the galvanometer equals that of the rest of the circuit.—J. CROCKER.

[52683.]—**Bartolozzi.**—Could any of your readers give me the address of where the Bartolozzi Exhibition was held about a year ago in London? I sent a picture, and it has not been returned. I have lost the address.—X. Y. Z.

[52684.]—**Platinised Silver.**—I have a lot of plates to platinise for Smee's batteries, and would like to know how much bichloride of platinum to use to, say, each square foot of surface of silver plate, without being wasteful.—GULLIVER.

[52685.]—**Octave Coupler.**—Will either of your esteemed correspondents, "Organon" or G. Fryer, kindly give instructions for making and fitting an octave coupler to a harmonium?—W. IRELAND.

[52686.]—**File-Cutting Machine.**—Will any one kindly give description of best file-cutting machine—the latest and best one made? and oblige.—T. J. HAMILTON.

[52687.]—**Florida.**—Will some of the many readers of this widely-circulated paper kindly give me information about the climate and products, &c., of Florida?—it being my intention to emigrate there. Is the climate healthy? Which part is the healthiest and best in general for the emigrant—North, middle, or South? What county would you advise me to go to? I heard fever was prevalent. Is it so—is it of a bad kind? Are reptiles dangerous there? I have heard the orange is the most profitable culture in the State. Is it so, and what county is it carried on most extensively in? Is it a good climate for bees? Are they plenty? Can they be had at a reasonable price? What sort of hives are used—skeps or bar frames? It being my intention to carry on bee-farming, perhaps, after a time, if I find it profitable. What sort of houses are there?—wooden, I suppose. Would it be possible for me to get agencies for the sale of English goods out there? Can I get carpenters' tools at a reasonable price, or would it be cheaper for me to bring them out from this country (Ireland or England)? Also, what articles of furniture and clothes ought I bring out? What sort of clothes are worn? Would it be wise to carry out feather beds, mattresses, or bed clothing, also ware? If some of the readers of the "E. M." who have been out there, who have practical experience, or even those who have not been out there, but who have a knowledge of the State from friends out there, or otherwise, would give me general advice all about the country, the best place for emigrant to go, and whether it is a good place for a doctor, &c., they would oblige me much. I write on behalf of others as well as myself. Also advice about other States would oblige.—F.

[52688.] **Crank and Treadle.**—I shall be obliged if any one who may have tried or studied the matter will inform me how much throw to give double crank for 4½in. back gear general work, with dimensions of treadle crossbars, so as to get power without too much movement of foot. Also price of chain band used for same.—CHARLELOI.

[52689.] **Gold Washing.**—Can any one give an account of an electrical contrivance designed to facilitate the discovery and collection of particles of gold in a "washing" by magnetism? Such was mentioned in one of the newspapers within the last two or three months.—WASHER.

[52690.]—**Patent Armatures for Dynamo-Electric Machines.**—Will some of our readers who are versed in patent law kindly indicate how near amateur electricians can approach existing patents for armatures of dynamo-electric machines without infringing the patents? For example: Can an amateur make for his own use and amusement a dynamo machine with armature resembling the Gramme, the Maxim-Weston, the Pilsen-Joel, or any other form of patent armature, without rendering himself liable to legal proceedings? If not, what form of armature may he safely imitate?—GALVANOPLAST.

[52691.]—**Assaying Silver Alloys.**—Will Mr. Allen, or some other practical assayer, kindly assist me in determining the quantity of lead to be added to an alloy of silver and copper to remove every trace of the copper? How many grains of lead to the estimated grain of copper? Also please assist me in determining the size and weight of cupel for each assay. Supposing an estimated five grains of copper in an assay, what weight of boneash will be necessary to absorb the lead and copper oxides from the assay?—GALVANOPLAST.

[52692.]—**Cleaning Sponge Cloths.**—Would some of our locomotive correspondents kindly tell me how the sponge cloths (used by fitters, cleaners, &c.) in the locomotive sheds at Crewe and other places are washed clean? Also position of steam pipes in the boilers, strength of soda, &c., and whether anything else than soda put in the boilers? I have a large quantity to wash, but I never can get them clean through.—[illegible]

[52693.]—**Watch Jobbing.**—Will any of your correspondents kindly inform me how to put a new cylinder into a Geneva watch, and also how to put a balance staff into a Geneva lever watch?—[illegible]

[52694.]—**White Furniture Cream.**—Would any reader kindly give me particulars how to make a good white furniture cream for cleaning and polishing? I have been trying for some time to make one, but cannot. Mine either dries on too quickly or smears the furniture, and will not polish.—[illegible]

[52695.]—**Electric Bath.**—Can any one tell me how to fit up an electric bath? What kind of apparatus to use, and how to apply it for the cure of nervous disorders, particularly general debility?—H.

[52696.]—**Silver Mounts.**—What kind of tools are used to get the frames of cigar cases up—those sort that are made with square tube with the inside cut away, or is the guttering drawn?—GEORGE EVERSLEY.

[52697.]—**Damp-proof Glue.**—Can some of the readers of our paper give me any information upon a formula for putting into glue, rendering it impervious to damp, and sets in three or four minutes so fast that the joints glued cannot be broken. There is an American in this country calling upon cabinet-makers and others offering the recipe for sale, £2 10s. I gave him two pieces of wood, roughly warmed: he warmed them, then warmed a lump of the prepared glue on the stove-pipe and glued the wood, rubbing them well together. In three minutes we could not break the glued joint, though we tried all means. This glue will be invaluable to me, if it will stand any length of time. Also, can any one give me information upon a means lately discovered for making thin veneer so pliable that it can be put on mouldings or any uneven surface as easy as papering it.—ALEX. FINLAYSON.

[52698.]—**Gas for Boiler.**—I have a copper circular horizontal boiler 22½in. long and 10in. diam. It has a central fireplace 6in. diam. running for 20½in. of its length, with a chimney at the end. I propose to heat it by means of gas with atmospheric burner. I should feel obliged to any one who could give me information as to how I could best arrange and make it so as to give out large amount of heat. Would this boiler be large enough to work an engine of 3½in. stroke and 1¼in. bore?—AMATEUR ENGINEER.

[52699.]—**Cement for Pavement Lights.**—Will some correspondent please inform me how to make the best cement for fixing glass in my pavement light? I find many of them are loose, and a source of danger.—C. LISSON.

[52700.]—**German Yeast.**—I want to sponge with a yeast or barm capable of keeping a biscuit-cutting machine going constant, having in hand when starting a batch of 560lb. of dough, which the machine will cut up in about three hours. Would "Cypher," "Cygnet," or any other of our readers, oblige by stating the best yeast to use, the proportion to 280lb. of flour, what temperature to use at when the bakehouse is about 65° F.? Whether quarter or half sponge should be used, and probable time taken before being ready for doughing? I have used compound brewer's and other barms—all good enough, but too slow. I have all information from Vol. XXX. to the present; but find nothing to answer my purpose.—EGO ALPHA.

[52701.]—**Water-Motor for driving Dynamo.**—Would any kind subscriber inform me how to make a small water-motor for driving a dynamo, something after the style of the Thirlmere? Whether a wood case of oak would be strong enough to stand the pressure of 40lb. to the sq. in.? If so, please say the best form for utilising power, thickness of case, and best form of paddles, &c., so as to get all available power.—A. E. WEBBER.

[52702.]—**Water Power.**—Will some fellow-reader inform me what quantity of water per minute will pass through a pipe 9in. diam., with a fall of 1 in 400?—FARMER.

[52703.]—**Sewer Gas.**—I should be glad to know approximately the percentages of the different constituents of sewer gas.—CHEMIST.

[52704.]—**Piano.**—I have a cabinet piano, the case, frame, soundboard, and strings of which appear to be as good as when new: but the action appears worn, and the felt on the hammers, though not cut, hardened with use. The tone is hard, and without much sustaining power: and some of the notes have a disagreeable metallic ring in them. Would a new action improve it much, and how much would it cost? It is six octave, and the action-frame is 3ft. 4in. by 3ft.—E.

[52705.]—**Spiral Wood-Turning.**—Can any person oblige by answering the following? Would a slide-rest be necessary, or is it possible to do with an ordinary lathe for spiral wood turning?—E. JOY.

[52706.]—**Bottle Batteries.**—I want a battery that when charged will remain good for, say, six or eight weeks, so that it shall be ready day or night to illuminate a five-candle lamp for surgical operations. Expense is not an object, so that I propose having two or three two-gallon bottle bichromate batteries, if these will last longer than the ordinary open jars. How long will the bichromate solution keep if the carbons are in it, but the zincs suspended? Possibly I might be six or eight weeks, and not require it, and then at the ninth week want it in a few minutes. Shall I gain anything by the use of the more costly bottle bichromate? Will "Sigma" and your other correspondent who kindly replied to my last, accept my best thanks for their courtesy?—SPECTATOR.

[52707.]—**L. & S.W.R. Brakes.**—I have been informed that the above railway use an automatic steam brake upon their engines, in conjunction with automatic vacuum brakes on train. I shall be glad if some of the numerous readers of the "E. M." will tell me how this steam brake is made automatic.—A drawing will be very acceptable.—H. W. HUDSON.

[52708.]—**Stop for Photo. Lens.**—I have a [illegible]-focus view lens, which will cover a 5 by 4 plate, with a [illegible]in. stop, but with a [illegible]in. stop the light is cut off the corners of the plate. At what distance from lens should stop be placed, relative to focus, single view lens, stop working in front? The rule for any focus would no doubt be useful to others as well as myself, now Mr. Lancaster is placing the lens within the means of most of us.—C. W. CLIFFORD.

[52709.]—**Fire Alarm.**—Can any reader recommend a simple and efficient apparatus for alarm in case of fire, in lieu of the ordinary bell? Are foghorns suitable? What distance can the sound be heard from, and what is the probable cost? Any information will be valued by—INSURER.

[52710.]—**Wheel Teeth Calculation.**—I wish to know by what method I may obtain the following calculation.—Take a given number, say 64,800, and give the rule for finding what three numbers, when multiplied together, will give the above number. The rule also when four or five multiples are required to equal a given number will oblige.—Clockmaker.

[52711.]—**Decoration of Jewellery.**—Will Mr. Widemann, or any other kind reader, give instructions or say where the same may be had for the decoration of the above by means of baths of alkaline plumbates and ferrates?—W. S.

[52712.]—**Coupling Railway Waggons.**—Will any reader give "methods" and full details of coupling waggons, without a man going between the waggons?—Historian, M.I.M.E.

[52713.]—**Painting Engines.**—To "Meteor."—Has the M. Ry. Co. decided to paint their engines brown instead of green, as several brown ones are running?—Historian, M.I.M.E.

[52714.]—**House Chimneys.**—I should feel much indebted to any of your practical readers who would kindly give me their opinion as to the safety or insecurity of chimney stacks of the following proportions: Height from parapet, 9ft.; breadth, 6ft. 7in.; thickness, 18in. The stacks have each three flues, but are constructed of only 4½in. work. They are in rather an exposed situation; but the masonry is good. The recent accidents from falling chimneys prompt me to make this inquiry.—Timidity.

[52715.]—**Steam Launch.**—Being desirous of making a little screw steam launch, would any of the readers of "ours" kindly tell me if I could make the ordinary open rowing boat into one? Its length is 12ft. by 3ft. broad. I should like to have engines of 1h.p. Would this be strong enough to do from 12 to 14 miles an hour on the river. Would any reader kindly also tell me where I could get such fittings? Any information that you can give me I should be most thankful for.—W. W. H.

[52716.]—**Lathe.**—I am availing myself of the clear and practical directions now appearing for making "A Cheap Lathe"; but as I do not intend to shirk the first difficulty, an iron bed, and should like (if successful) to go on improving my lathe, perhaps "J. H." will be kind enough to give the following information—viz., Directions for making, and dimensions of, the arms and other extra parts to casting of headstock for carrying back-gearing and screw-cutting attachments, also short description of the way to arrange back centre keeping the same end in view.—Headstock.

[52717.]—**Wollaston's Battery.**—Will any correspondent inform me what is the matter with my batteries? I have made them in the usual way, and in two or three hours after they were put together the zinc plates went black and gave off gas. I have tried the acid weaker, and also fresh zinc plates, but with no better results; the mercury seems to dissolve off the plates.—H. C.

[52718.]—**Dog Poisoning.**—Will one of our chemical readers tell me the dose and name of the most merciful poison for destroying a very powerful dog, a great favourite, but pronounced unsafe to keep. Local chemists seem very hazy on the point, seeming to know but little of the painless, or otherwise, action of any poison. Would laudanum have painless and sure action?—M. C. H.

[52719.]—**Flooring for Sheds.**—I am about to erect some hundreds of square yards of sheds under which to manufacture chemicals, can any of your readers tell me from their own experience how to form a flooring which shall be water and neutral liquor tight, and be cheaper than flags. There may be some form of concrete which would answer the purpose. Any hints about this matter, together with cost per square yard, will be valued.—P. H.

[52720.]—**Telephonic Patents.**—Can any one tell me if the Bell Telephone and Blake Transmitter is patented in Australia, and if so in what part? Is there a good opening in Queensland for a telephonic engineer starting on his own account? What good instruments, both receiver and transmitter, can be legally used in this country and bought at a moderate price. Is the cup and ball microphone a good and legal instrument for this country.—Telephonic.

[52721.]—**Electrical.**—Would any of your readers kindly answer the following:—How Coulomb's torsion balance is used for the purpose of comparing the quantities of electricity in the same Leyden jar on two different occasions? Also the formula in Ganot's "Physics," page 646 and 647, for charging by cascade arrangement. I am not a mathematician, and should be obliged if your readers would give results in arithmetical numbers, and not mathematical formulæ.—R. R. R.

[52722.—**To Mr. Lancaster.**—I am making a battery of twelve cells, two copper plates and one zinc; the coppers are eight by six, and the cells are wood, charged with sulphuric acid and water. Would it be best to line the cells with sheet lead inside or paint them with pitch, and how many incandescent lamps will it light, and how long will the battery last?—I shall be much obliged.—Z.

[52723.]—**Chimney.**—I am about to erect a chimney for a works, and should feel obliged if you would direct me to any previous articles in your journal bearing on the matter, or to any good book containing the requisite information. Failing this, some of your readers might be able to help me. The one proposed to be built is to be about 60yds. high, but sufficiently strong to carry another 20 if found requisite. What I want is the proper bottom and top inside diameters, and thickness of walls; to what extent a firebrick lining should be used. Also information about the requisite precautions to secure a sound foundation? what are the relative advantages or otherwise of the round, square, or octagon form? The chimney in question will have to carry away the products from about 150 tons of coals per week.—P. H.

[52724.]—**Detaining Luggage.**—Would any legal friend express opinion as to the right of a tradesman to detain luggage under the following circumstances? A., on a visit at a watering place, buys frequently small items at a grocer's, B., and pays cash down, taking no receipt. Shortly before A.'s departure B. sends in an account for a few shillings said not to be paid for goods on a certain day when obtained as usual. A.'s cash book shows the items were paid for. B. on morning of A.'s quitting meets A. at railway station and threatens to stop a trunk "as the law permits." A says: "Do it at your peril," and B concludes "not."—M. C. H.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 9, and unacknowledged elsewhere:—

J. A. Campbell.—H. Trick.—W. Nolan.—Maynard and Harris.—W. H. Sellens.—Blakey, Emmott, and Co.—R. Prentice.—E. J. Piper.—South London Machinists' Co.—G. J. Hewson.—J. Place.—E. M. Richards.—Rev. Dr. Richards.—A. J. S. Compton.—T. Barker and Co.—M. D.—C. J. N.—R.—W. J. Grey.—E. Beaumont.—O.—Chemicus.—D. Williams.—Unsuccessful.—M. A.—Delta.—W. H. E., Coventry.—A Blacksmith.—J. E. Floyd.—W. D. B., Dublin.—H. R.—Inventor.—T. J. O'Connor.—A Sheffield Workman.—W. Jones.—Clock.—X.—Shakespeare.—T. Usher.—A Fellow of the Royal Astronomical Society.—Leonard Marshall, M.A.—J. Copcutt.—H. Sadler.—C. E. Stretton.—Model.

W. M. B. and Anxious. (Paint for blackboards has been given several times. Some recommend staining—ebonising in the way described the other week, and rubbing over with heel-ball until glossy. Others paint with several coats of lampblack, the last being mixed with turpentine only; another recipe gives finely powdered coke as an addition to the black paint. On p. 188, Vol. XV., there are two recipes for "liquid slating" for blackboards, which are shellac varnishes to which powdered pumice or fine emery is added, and lampblack or ivory black. See also pp. 168, 190, Vol. XV.)—S. Taylor, Leicester. (If it is a Rubens, you should communicate with Mr. F. W. Burton, director of the National Gallery, Trafalgar-square. If there is any likelihood of its being genuine he will no doubt send an expert to see it.)—Thistle. (See list of Back Numbers in this col. last week—Copying Processes. You have inverted the proportions of glue and glycerine. It should be 1 glue to 4 glycerine. Add whiting to give body and colour. 2. Should be all wool.)—J. A. C. (We answered your query on p. 332, middle col. The watch wants timing and adjusting for position, as has been explained many times. If your watchmaker does not know that, take it to another man.)—M. P. H. (Indiarubber dissolved in bisulphide of carbon or mineral naphtha.)—E. Webb. (1. Directions for making batteries in many numbers—the last, for instance; but see the list of Back Numbers. 2. If the notice is legal, quit at the time appointed, and pay the rent due at the time.)—A. P. S. (There is no book on the subject; but you will find articles in the cyclopædias, and some replies on the subject in recent numbers. We are not aware that there is any new process.)—P. (Sharpening and setting saws in Vol. XXXVI., pp. 296, 5:5, with illustrations.)—W. L. Willis. (See the indices. Nos. 16 or 18 for primary and 34 or 36 for secondary. 2. The duration depends on the work it is made to do. 3. We cannot say. We do not know any one who has measured such a cell. You seem to have forgotten the manganese.)—W. Thompson. (Your sample appears to have been prepared by spreading over it a solution of pitch in mineral naphtha, mixed with boiled oil; but it may be gas tar asphaltum boiled with linseed oil and thinned with turpentine.)—Tricyclist. (Similar request inserted. 2. Several have been given.)—P. Ward. (Kindly read the heading to "Unanswered Queries." It will be entered in due time if not answered.)—Astro. (The compass is of very little use for such a purpose. We have given several methods; perhaps the simplest is that on p. 568, No. 909.) Nil Sine Causa. (You must get some one to take a copy to Stationers' Hall, fill up the form, and pay 5s.) E. Robinson. (Answered very recently—see replies to 51944. The other method is with copper bronze powder mixed with varnish—Bessemer's paint.)—Keen Lover of Music. (You can find them in the lists or in the Post Office Directory; but as a matter of fact any newsvendor who understands his business will not only tell you the titles, but offer to get copies for you.)—Coup d'Essai. (It depends on what you want to do. If for bell-ringing over a long wire, connect zinc of one cell to carbon of the next.)—Paul Changer. (We can only refer you to some elementary textbook, for without knowing what you mean it is waste of time to guess. Perhaps the reflection that no one would use the secondary if he could get the effects with the primary, may solve your difficulty.)—Learner. (See some of the handbooks of the art, or look up our back volumes. We cannot afford space for queries which involve replies that may or may not be answered owing to the indefinite nature of the question.)—Ignorant. (Kindly look at the subject in back numbers. See the Edco Battery, p. 379.)—One Wishful to Learn. (What is the matter with them? You can learn by reading the plain instructions on pp. 180, 244, 553 of the last volume.)—A Six Months' Subscriber. (Will do for the return—that is all. You must have a line wire for the current to the bells. 2. The only books we know are Spretson on "Casting and Founding" (Spons), "The Brass-Founder's Manual" (Lockwood and Co.), and Overman's "Moulder's and Founder's Guide" (Sampson Low.)—Volt. (It is shown on p. 101, Vol. XXXIII.; also in another form on p. 565; but why not go into the Patent Office Library and read the specification.)—G. R. B. (Queries asking for full particulars of an electro-motor without stating the size cannot be inserted. You will find several illustrated in back volumes, and can take a choice, so as to pick that one which will be easiest for you to make. How will the one on p. 95, No. 914, do; or that in No. 908, p. 554?)—Unique. (An "electric motor for driving a lathe," is not definite enough. What size lathe, and what work is the lathe to do? However, see previous answer, and look through the indices.)—J. K. (Leclanché cells are not suited to electric-lighting purposes. 2. If you mean what would be the cost of lamps of the power specified, it would be more than the same light from gas.)—Aurora. (Have you referred to the back Nos. given in the list which appeared in this column last week? You want different sized wires to those you have.)—Impudent Telegraphist. (At any dealers in such material. See our advt. pages. 2. The question is not clear, but we suppose they are soldered. 3. Several, we believe; but the hand-stamping is preferred.)—Pain in the Chest. (Would you really take anything and everything that might be guessed? Better consult another medical man, and tell him as near as you can what did you so much good before. You must recollect that you are older.)—W. Watson. (Not possible, without sacrificing something. The usual size has not been adopted for nothing; but look up the subject in back numbers, and you will probably find something to suit. There must, however, be something like the present length.)—A Youngster. (All you want is a simple revolution indicator which is applicable to any sized wheel. A table, easily calculated, shows how many revolutions are equal to a mile. If you must make it indicate the distance, you will find the method of calculating trains in several back numbers, or you could get the idea from a gas-meter index. Doubtful whether any of the "movements" you refer to could be utilised.)—W. F. James. (A variety of ellipsographs have been illustrated in back volumes. See p. 593, Vol. XV., p. 60, Vol. XII., p. 448, 548, 595, Vol. XI.; also in earlier volumes. See Stanley's book on "Drawing Instruments.")—G. M. or S. M. (For painting lantern-slides, see p. 226, last volume, and the indices generally.)—Miller. (An Otto gas engine would be much the more economical of the two, and so much cleaner—a consideration in your case. Makers would give all particulars as to size of main, &c.)—A. Mee. (In type).

The English Mechanic
AND WORLD OF SCIENCE AND ART.

FRIDAY, JANUARY 18, 1884.

AMERICAN LOCOMOTIVE PRACTICE.*

ALTHOUGH the average speed of trains in the United States is some 20 per cent. below the mean speed of trains in this country, all things considered, the service controlled by the American engineers compares favourably with any in the world. There is, we need scarcely say, a considerable difference in the conditions, both with regard to the engines and the carriages, and also in the matter of road—a most important factor when high speeds enter into the question. The American style of carriage is well-adapted at all events for the long-distance journeys; but just as there is little reason to imagine it will ever be adopted here, except in special circumstances, so there is some reason to think that in what we may call their local or metropolitan service, American railway managers may, before long, adopt the English or common pattern, with improvements suited to the tastes of their patrons. The question as to which is the best style of locomotive has long been debated by engineers in this country and America, and recently a suggestion was made that a first-class English engine should be bought by some of the American companies and tested on their lines against the best locomotive produced in their shops. Probably the best locomotive has not yet been devised, even for any given section of line and class of traffic, and it is certain that locomotive designers in this country have not arrived at finality, though it may very well be doubted whether some recent changes in matters of detail are altogether improvements. The American engineers at first copied English builders and made locomotives with single drivers; but, as is their wont, they quickly made improvements, and we are not disposed to dispute with Mr. Edwards the dictum that the American locomotive of to-day is "one of the most perfect pieces of mechanism wrought out by the hand and mind of man." We must, however, be allowed to say that another of the "most perfect pieces of mechanism," &c., is the English locomotive of to-day — though "most perfect" must be taken really in a comparative sense, for the locomotive, whether in the United States or in England is not quite perfect, though wonderful enough to those who really understand its construction. The standard passenger locomotive of the American lines has four-coupled drivers with a leading four-wheeled bogie truck, the latter arrangement having been apparently first introduced—at least so far as a four-wheeled leading truck is concerned—by Mr. M. W. Baldwin, in an engine he built for Mr. E. L. Miller in 1834. For freight trains, engines having six and even eight coupled driving wheels are used; but, as a rule, in those cases the front is carried by a two-wheeled truck. In the standard, or "American," engine, as it is called, the drivers rarely exceed 5ft. 6in. in diameter, and very frequently are nearer 5ft., but latterly, for fast traffic, some standard engines have been built having drivers of 6ft. 6in. diameter; and at least one well-known engineer considers that for certain fast lines single drivers of large diameter would be better than the present rather small four-coupled wheels. The standard type has undoubtedly done good work; but it is not unlikely that before long the American builders will return to some of the models that were made in 1849. About that time several locomotives were built having 7ft. single drivers, and at least seven having single drivers as large as 8ft.; some of these last having the rather extraordinary cylinder dimensions of 13in. diameter by 38in. stroke! For the last three or four years, engines having single drivers of 6ft. 6in. diameter have been used to work the fast trains on the Bound Brook route between Philadelphia and New York, and as the gradients of the line are easy, and it seems fast trains will pay, there is a possibility that Mr. Barnet le Van's idea of 90 miles an hour will be accomplished some day. A glance at the railway map of the United States will show, as the fact is, that there must be considerable rivalry between the lines running to Philadelphia from New York, or rather Jersey City, and as one route is about a mile or so longer than the other, it was considered an achievement for the Reading railroad to do the journey in less time than was taken by the Pennsylvania line. Between the points where speed can be maintained the average rate for one train was 57·6 miles, and of the other 49 miles. Since that trial the Pennsylvania line has done better, and now runs the fastest train in America over a distance of ground—the fastest in the world for a journey of more than 900 miles. The United States is the country of long distances, and has the advantage of a "limited express" with a journey of 912 miles, and only seven stops, which is accomplished in the excellent time of just less than 25½ hours. It must be remembered in considering this performance that not only does this train slow through many junctions, but it also crosses many busy streets and passes through several towns on the level, so that after getting beyond Philadelphia, a run of twenty miles without checking the speed is rare. The run from Jersey City to Philadelphia is the fastest portion, and is accomplished at an average speed of 45 miles an hour, while the remainder of the journey is run at an average of 34 miles, the mean rate over the whole 912 miles being 35·29 miles an hour. The stops are made at the ends of the sections to change engines, which are mostly of the standard four-coupled type, but with 6ft. 6in. drivers. They weigh, roadworthy, including tender, 74 tons; and as the train usually consists of five Pullman sleeping cars and one dining car, the total weight to be hauled is about 274 tons. Throughout the journey the speed is continually varying from 30 to 60 miles an hour; but on the clearest portion of the line the rate for a few miles is about 70. The firebox of the engine used for work of this kind is about 10ft. long; so that the fireman must be an expert in his way to keep the fire level and bright and the steam gauge steady at 130. An injector is used to feed, and is kept continually at work during the trip. We think that most railway men will agree with us that this journey of 912 miles in less than 26 hours will compare well with any run in Great Britain, when the conditions are considered, and it is in itself sufficient evidence that the locomotive engine in the United States has reached a high degree of excellence. Those who wish to obtain, as it were at a glance, a good idea of American locomotive practice will find it in Mr. Edwards's book, the title of which we give below, for on one page we have seventeen little diagrams of the engines shown at the Centennial Exhibition held in Philadelphia in 1876, and the following pages give in table form the measurements or other particulars necessary to form a complete idea of the various types illustrated. Mr. Edwards's work forms, in fact, a textbook of the locomotive specially adapted to American practice, and is an all-sufficient guide to the workman and to the designer. In his chapter on the link motion, the author falls into the error of attributing that almost invaluable invention to George Stephenson. The fact is that in 1842 a Mr. Williams, a gentleman apprentice in the works of R. Stephenson and Co., suggested something of the kind; but the link-motion, as we know it, was worked out by Mr. W. Howe, at that time an *employé* of the Messrs. Stephenson and Co., who was rewarded by the present of twenty guineas. Mr. Hutchinson, the manager of the works, seems to have had something to do with the invention—he is credited with suggesting the notches in the quadrant—and there is also a claim for Mr. Jackson, a miner, who is alleged to have given the idea to Howe. Be that as it may, it is certain that Mr. Williams conceived the original idea, and that Howe was the first to exhibit a really practicable model. The Stephensons had nothing to do with it beyond giving it their countenance. In Vol. XIV., the question is ably argued out, and on p. 328 of that volume will be found a diminished copy of the original drawings sent to the North Midland Co., in order that they might apply the link motion to their engine No. 71, the first that was fitted with the link. Besides the matters which belong exclusively to the locomotive, Mr. Edwards's book contains much useful information relating to workshop practices, and the tables which he appends complete a volume which, we doubt not, will be of great assistance to the future locomotive designers, drivers, and firemen in the United States. Forney's "Catechism," which was published in 1875, and which we reviewed on p. 601, Vol. XXI., is a work which is more purely practical; but Mr. Edwards has endeavoured to instruct his readers in the theory and the principles of the practice, and with these two books in his library the student will have little difficulty in understanding that wonderful creation of mechanical genius — the modern locomotive.

ELECTRO-MAGNETS.—II.

By JOHN T. SPRAGUE.

(Concluded from page 355.)

18. THE maximum attractive power to be developed in iron was found by Joule to be 200lb. per square inch of core, which is equivalent to a force of 13,800,000 dynes per centimetre. Prof. Rowland gives the capacity of iron at 1,390 C.G.S. units per cubic centimetre; but various authorities range from 400 to 1,000 for steel, and, as will be understood from secs. 15 to 18, each quality of iron has its own specific capacity, to be ascertained only by experiment.

19. The selection of the suitable size of wire is governed by the resistance of the rest of the circuit. For maximum work, the resistance of the magnet should be equal to that of all the rest of the circuit, including battery. For rapid action, as in a vibrating armature or telegraphic relay, the resistance is made much lower than this, to prevent the counteracting influence and damage of extra currents. But it should be understood that "resistance" is employed in this way merely as a mode of measuring and comparing the wires of different sizes and lengths, which can be put into the helix of required dimensions. Resistance, as such, must be kept down by using high conducting wire.

20. Various formulæ are given to determine the sizes of wire required; but I prefer, for the sake of general readers, to deal with the subject physically rather than algebraically. A helix is a certain space which

---

* Modern American Locomotive Engines. By EMORY EDWARDS, M.E. Philadelphia: Henry Carey Baird and Co.; London: Sampson Low and Co.

VOL. XXXVIII.—NO. 982.

[illegible] only [illegible] taking the space [illegible] and [illegible] the square of the diameter [illegible] with the [illegible] external area, and [illegible] length given [illegible] weight as [illegible] copper. [illegible] may be made [illegible] size [illegible] wire and the nature of the covering and also with the skill [illegible] winding [illegible] helix. In the [illegible] it will vary from [illegible] gauge. The [illegible] multiplied by these ratios will give the actual weight of metal which can be placed [illegible] the helix.

21. Having thus the weight of metal at disposal, W, and the resistance it is to give, R, we can ascertain the diameter of wire to be used. In fact, a rule-of-three sum will give us the [illegible] —

As W [illegible]

A reference to the table given in No. [illegible] of the present volume will then show the suitable size of wire, or it may be calculated from the constant of 1 mil. wire [illegible] = square of area in mils. of [illegible] the [illegible] wire.

Therefore, the square root of the quotient gives the area, and the square root of this the diameter.

The logarithmic calculation is exceedingly simple, as it consists only of deducting the logarithm of the [illegible] per lb. from [illegible] and dividing the remainder by [illegible] which gives the logarithm of the diameter required.

22. The simplest mode of ascertaining the [illegible] is to prepare a [illegible] in which [illegible] wire. [illegible] these. [illegible] turns per [illegible] wire will [illegible] which would [illegible] is the [illegible]

[illegible] be considered in [illegible] the definite [illegible] be required to perform [illegible] expenditure [illegible] be measured in foot-[illegible] of the magnet [illegible] current passing it will [illegible] which, for the time [illegible] resistance added to that due [illegible]. In designing the electro-[illegible] necessary therefore to arrange [illegible] to the dimensions which [illegible] attractive power which is [illegible] necessary. Then to adjust [illegible] wire and its resistance to the [illegible] of the circuit, because, while a [illegible] wire may give the required conditions [illegible] a fine wire may be [illegible] any considerable distance. [illegible] battery power must be arranged [illegible] merely the current required to [illegible], but the electro-motive [illegible] to pass that current when [illegible] doing work. It is here that [illegible] usually arise.

[illegible] a battery and magnet with a [illegible] in circuit, and note the current [illegible] the magnet work to do in [illegible] weight, and the same current [illegible]. This seems a paradox, [illegible] should pass when it [illegible] work than when it merely tra-[illegible], but it is easily explained. [illegible] and magnet have each a [illegible], and the battery an [illegible] to pass a current of [illegible] for the con-[illegible], that the added [illegible] the current [illegible]

Then [illegible] that the work is equivalent to a [illegible] added to that of the wire. Now the energy expended is in the ratio of $C^2 \times R$, be the resistance of what order it may. Hence, we have, at first energy supplied by the current $3^2 \times 2 = 18$ joulads per second.

Under the second conditions, we have it $2^2 \times 3 = 12$, less energy supplied by the reduced current to the increased resistance.

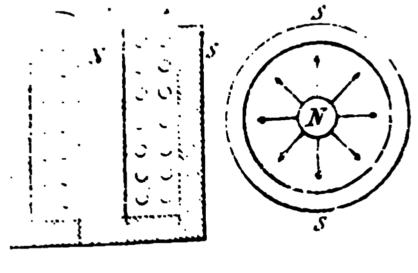
But in the first case the whole 18 joulads are expended in heating the battery and wire; in the second case, only 8 are so expended, while 4 are employed in work.

25. If, then, the magnet is so arranged that it will require 3 ampères to do its work, it is evident the E.M.F. must be increased in proportion to the extra resistance represented by the work; it must, therefore, be raised to $C \times R = 3 \times 3 = 9$ volts, and then we shall have energy $3^2 \times 3 = 27$ joulads, of which 18 are used in battery and wire as before, and 9 remain to do the mechanical work. Therefore, in all cases, the battery must supply the current required while work is doing, not merely that calculated from the measured resistances.

26. As usually constructed—that is, in the horseshoe form—the electro-magnets do not utilise all the magnetic effect of the current, which acts externally as well as internally, but in the opposite direction. The armature is magnetised, of course, but only by induction from the core, and part of the power must be diverted to the external field of the helix. This external power may be utilised in various ways.

27. A few years ago, great claims were made as to the advantages of surrounding the helix with an external tube of iron connected to the core at the lower end by a disc of iron. This was patented under the name of the "[illegible]" magnet—a barbarous word invented to convey some idea of exaltation; but the construction had been frequently employed before. Fig. 6 will explain it.

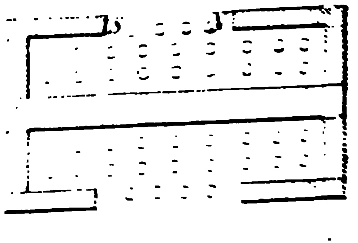
Fig. 6.



It will be seen that though there is only one core, this is still a true horse-shoe magnet, the other arm being a cylinder surrounding the core. The effect is to produce an intense, but very limited, field, represented by the arrows, giving, no doubt, great holding power, but with attraction exerted only at a small distance.

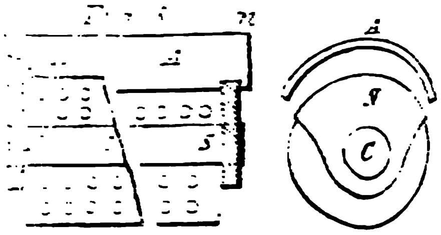
28. A modification of this is employed in some electric bells, which is shown in Fig. 7.

Fig. 7.



In this a cylinder is placed on each end and the opening in which the [illegible] is produced is at the middle of the core. The cylinders should be more open at the lower side, as shown in dotted lines, in order to concentrate the polar forces in the upper part where they can act on the armature.

28. Perhaps the greatest power may be obtained by a further modification of my own, in which the external action of the current is taken up by the armature, which is thus magnetised by the current, as well as by induction. Fig. 8 shows this:—



C is the core, fitted with two pole pieces, N, S, extending over one-third of the end of the helix: A is the armature in which the outside action of the current produces poles *n s* opposed to those of the magnet, so that a powerful attraction draws down the armature which is made as part of a cylinder fitted to the pole pieces.

OBJECT-GLASS WORKING.—X.

By "[illegible]."

THERE must be great care used, if dry polishing is adopted, to remove all grease from the surface of the lens. To insure this, as well as to cleanse the surfaces for examination, a weak acid dip is used after the smoothing. This dip is applied with a sponge and washed off afterwards with clean water. The proportions I find effective are 1 part of sulphuric acid B.P. to 6 parts water. It will astonish those not used to this, to find what a number of occult scratches and other defects are brought to light, when the deceptive top glass got in smoothing is dissolved off. It is not possible to give the time required to polish a given sized surface, but two considerations are here given. First, there is a little loss of light if the glasses are not so highly polished as the metal will permit. Second, the longer the surface is [illegible] the more the marginal error will increase in the hands of the inexperienced. It is very important in either method of dry polishing to keep all [illegible] as we are working. It is well also to brush the polishers every half hour with a soft brush, to remove the glass which adheres to the paper as it is polished off the lens. The method, when the stationary tool is used, consists of a continuation of straight, or straight varied with elliptic, strokes, keeping up an even pressure and a gradually increasing rotation of the lens. The thumbs and two first fingers of both hands will give the necessary pressure as well as can be given. With the [illegible] polisher the left hand is occupied with the wheel handle. The right hand only can be used for holding the lens: the thumb and three fingers are used, the tips of them being [illegible] sufficient to keep the lens down. For the [illegible] lens in this case the lateral stroke can bring the lens one-third of its diameter outside the margin of the tool with advantage. The rotation must be kept up, increasing from, say, [illegible] rotation of the lens to five turns of the wheel to [illegible] rotation to [illegible] turns of wheel to finish with. Paper, although giving [illegible] yielding surface, can be made with the [illegible] to give an elliptic, or even a parabolic, figure. The [illegible] at which the pressure affects the surface I use as a factor [illegible]. It would be impossible to give [illegible] that can be made in the [illegible]. It will, perhaps, assist the [illegible] how a concave surface may be [illegible] say, a parabolic figure by [illegible] pressure on the edge. A cork of the same [illegible] as the lens is used, with parallel sides and about [illegible] high. The "cake" [illegible] this cake at the edge. The polishing [illegible] until the test shows we are right [illegible] or under-correction is [illegible] a larger cork can be used, and the [illegible] be [illegible] in zones near the centre of the *rotating* tool. If a stationary tool be used, the polisher can be widened, or, rather, a wider one put down, of the same paper as the original one we began with. By acting upon this illustration, it will not be very difficult to so regulate or proportion the size of the cork back that, in conjunction with a suitable position on the rotating tool, or a suitable width of polisher on the stationary one, we can give our surfaces the needed figure. I do not see that by any possibility measurements can be of anything more than approximate value, every slight difference acting, as it does, in so greatly altering results. Minute differences in paper thickness, differences of pressure by different hands, even the temperature and pureness of the powders used, are each and all productive of great deviations from any laid-down rule. I do not state this to deter, but rather to incite to experiment.

Years ago it was my privilege to work with one of the great Dollond's o.g. workers. I confess that as I look back I am surprised at the comparatively primitive method, or rather want of method, that prevailed in the old days, and yet what good results were obtained. The mode was simplicity itself compared with the elaborate machinery of the present day as used in our best firms. I think a description in brief will interest our readers, so I will endeavour to give it.

The lenses, roughed up as usual, were cemented on an iron back with pitch: these backs each had a screwed boss, so that they would screw on a post set firmly in the floor. The tools of brass, the same size as the glass, also screwed on this post. The convex lens, smoothed beautifully (at the top), was now screwed on the post in place of the tool. A strip of lutestring silk, about four-fifths the diameter of the convex lens, was stuck down on the tool with a mixture of pitch and turpentine; when this was dry a good "seasoning" of putty powder, shaken out of a pepper-box, was applied and well wetted and rubbed into the silk. A wooden handle was screwed in the boss of the polishing tool, and the polishing, figuring, and finishing commenced. A regular sweeping stroke, showing the centre of the lens each time, was applied for a few hours, and then the lens was "knocked off." The same process did for the concave lens, with the exception that it was kept upwards and the tool was entirely covered with silk. Now came the testing, first on the dial. If it did not define *that*, one side after another was resmoothed and repolished until the dial (a good watch dial, with a very small name on it) was defined. Then came the star testing, which was a repetition of the other. Smooth over and polish over until good enough, with occasional flattenings and deepenings for colour correction, as alterations were made in the tools through the continued working. With regard to the method used for centring the lenses, which was done on a hollow mandrel, I do not think much improvement can be made upon it. This description will show that there must be individual skill at the botton of it all, or it is questionable whether even a good result could be got. Much pluck and patience and great powers of endurance had this old gentleman, and very good are his glasses, even now-a-days.

(*To be continued.*)

MANUFACTURED BRANDY.

UNDER the title of improvements in the manufacture of alcohols a patent has been granted in this country to an invention which is intended, by reducing them, to facilitate the removal and shipment of alcohols, and also to convert a quantity of plain spirit into Cognac brandy. The invention is a communication from M. Adrien Ralu, jun., of Ermont, France, and the patent covers several processes, for the result desired may be obtained in different ways —e.g., by distillation, or by raising or lowering the alcoholic strength by means of spirits having a flavour similar to that of Cognac, by the addition of essences and ethers, by maceration, or by lowering the degree of alcoholic strength by means of fruit juices. In operating by distillation, 1 kilogramme of juniper berries, 10 kilogrammes of prunes, and 1 kilogramme of orange blossom are added to every 100 kilogrammes of grape pulp that is to be distilled. This is left to macerate 24 hours, it is then distilled, and afterwards about half a litre of pure glycerine is poured into the alcohol thus obtained. In operating by reduction of the degree of alcoholic strength by means of spirits, for every 100 litres of superior corn or molasses spirit of 95° to 96° alcoholic strength by Gay-Lussac's centesimal alcoholometer, 13 litres of rum, 6 litres of cherry spirit, and 4 litres of Hollands gin of 49° to 50° strength when mixed are added, thus bringing down the strength of the whole to about 90°. Half a litre of pure glycerine is then added. In the process by raising the degree of alcoholic strength, the reverse is the case—i.e., rum or Cognac of 54° to 55° strength is brought up to 90° by the addition of superior corn or molasses spirit, and afterwards adding per 100 litres of this mixture, 3 litres of cherry spirit, 1 litre of Hollands gin, and half a litre of glycerine. In operating by addition of essences or ethers, for every 100 litres of alcohol of 95° to 96° strength by Gay-Lussac's centesimal alcoholometer, 12½ centilitres of essence or ether of Cognac, commonly sold under the name of flavour or essence of brandy, and a half-litre of pure glycerine are added; the whole is then macerated with 10 kilogrammes of prunes for about a fortnight; it is then strained and filtered. In operating by maceration, for every 100 litres of alcohol as above 15 kilogrammes of prunes, 250 grammes of juniper berries, and 125 grammes of black tea are added, and the whole left for about a month to macerate, after which it is strained and filtered and half a litre of pure glycerine added. In operating by reduction of the degree of alcoholic strength by means of fruit juices, for every 100 litres of alcohol of from 95° to 96° 12 to 15 litres of pineapple juice and 1 kilogramme of pineapple skins are added; the whole is left to macerate for about a fortnight, it is then filtered, after which 4 litres of Hollands gin and half a litre of glycerine are added. By adding an equal quantity of water to alcohols obtained as above, they are, according to the patentee, changed into Cognac of quality varying according to the nature of the ingredients used.

THE LATE MR. J. H. DALLMEYER.

THE death is announced, in his 53rd year, of Mr. John Henry Dallmeyer, optician, whose name has been long associated with the production of some of the best optical work in England, especially lenses for different branches of photography. In 1849 he left Germany, his native country, and came to England, entering the house of the late Andrew Ross, the founder of the well-known optician's business bearing his name. Mr. Dallmeyer's attention was at first devoted principally to the construction of telescopes, for which, in conjunction with Mr. Ross, he computed a large number of formulæ. At his death, Mr. Ross bequeathed to Mr. Dallmeyer the bulk of his optical appliances for the manufacture of astronomical telescopes. About this date (1855) photography began to be popularised by the general adoption of the collodion process. Mr. Dallmeyer quickly discovered that the photographic lenses then in use stood in great need of improvement in every direction. In rapid succession he produced lenses for landscape and portrait photography, and it is greatly owing to his efforts that English lenses now rank second to none. He was specially commissioned to provide several of the telescopes and photographic appliances used by the different Government expeditions for the observation of the recent Transit of Venus, and his telescope object-glasses are in high repute among the leading astronomers. For some time past his health had been precarious, and, whilst taking complete repose from work, on the voyage to New Zealand, he died on the 30th ult.

ALCHEMY AND MODERN SCIENCE.

THE following is an abstract of the last three lectures of the series delivered by Prof. Dewar, F.R.S., at the Royal Institution on "Alchemy in Relation to Modern Science." (See pages 382, 406.) Prof. Dewar began by reminding those who had followed the history that hitherto chemical research had been extricably mixed up with other extraneous matters, such as physical and metaphysical speculation about the constitution of the universe and so forth. This alloy added very much to the difficulty of the inquiry, which was further complicated by the fantastic notation employed by the alchemists from very early times in speaking of the things of which they treated. They used a secret language in teaching their occult science. Water and the other elements had each its own symbol. Each of the seven metals was denoted by the symbol of one of the members of the solar system as known to the ancient world, gold by that for the sun, silver by that for the moon, and quicksilver, copper, tin, iron, and lead by those for the planets Mercury, Venus, Jupiter, Mars, and Saturn respectively. Moreover, each had its mystical relation to its day of the week. These, together with the letters A B R A C A D A B R A, arranged in a sacred triangle and curious applications of the Pythagorean doctrine of numbers, were freely used by those versed in that Cabalistic lore which was traced back to Adam. The names of some of the writers on alchemy and titles of their works were cited. Zosimos wrote, "On the Divine Water" and "On the Method of Confecting gold;" Heliodoros, "Of the Sacred Art of Chemistry;" Theophrastos, Archelaos, Pelagois, Ostanes, "Of the Sacred Art;" Hierotheos, "Of the Stone of the Philosophers" and "Of Gold-making;" Olympiodoras also wrote "Of Gold-making." The Arabs were wonderful compilers of such learning, which from them passed through the Moors into Spain and the whole west. The words alkali, alcohol, borax, and many other chemical terms were Arabic. This literature proved that the alchemists had added to vinegar and other vegetable acids the spirit of nitre and the spirit of ammonia or salt. They had found that, as shown by the lecturer, the spirit of nitre (our nitric acid) would dissolve all the other metals known to them, but would not dissolve gold, which, however, yielded to what they termed *aqua regia*. This was nothing but a mixture of the spirits of nitre and salt (our nitric and muriatic acids). They knew besides that by the union of acids and alkalies fresh substances, unlike either, were formed, which they termed salts, as we did still. Nor were the ancient alchemists ignorant of the result of the action of the acids on metallic calces, the name given to the residuum left in the crucible after the roasting of the metals. On treating a calx with an acid they found that a solution resulted identical with that produced by dissolving in the acid the uncalcined metal. Experiments verifying these elementary but momentous conclusions, already reached by the alchemists, were repeated for the instruction of his youthful audience by Prof. Dewar. An experiment of another kind, namely, the coating of iron with copper by plunging it into an acid solution of the latter, it was remarked, might have fostered the delusion of the alchemists about the transmutation of the metals. Of course, a fresh application of the acid to the copper coating proved to the young students how baseless was the fancy. After a reference to Roger Bacon (1235) as the first great English alchemist, the lecturer reminded his audience that the real starting point of modern science must be dated from the investigation of the laws of motion by Galileo and Kepler, whose discoveries culminated with Newton. Galileo in 1639 discovered that the vibrations of the pendulum, short or long, take the same time, thus giving us an exact measure of time. The discovery led up to its use in determining the shape of the earth as well as our planet's density, and in demonstrating its rotation on its axis. The lecturer concluded with an eminently successful repetition of Foucault's experiment in 1851, the seeming deflection of the pendulum, taken on a measured scale, minute by minute and always in the same direction, proving to demonstration the real diurnal motion of our planet.

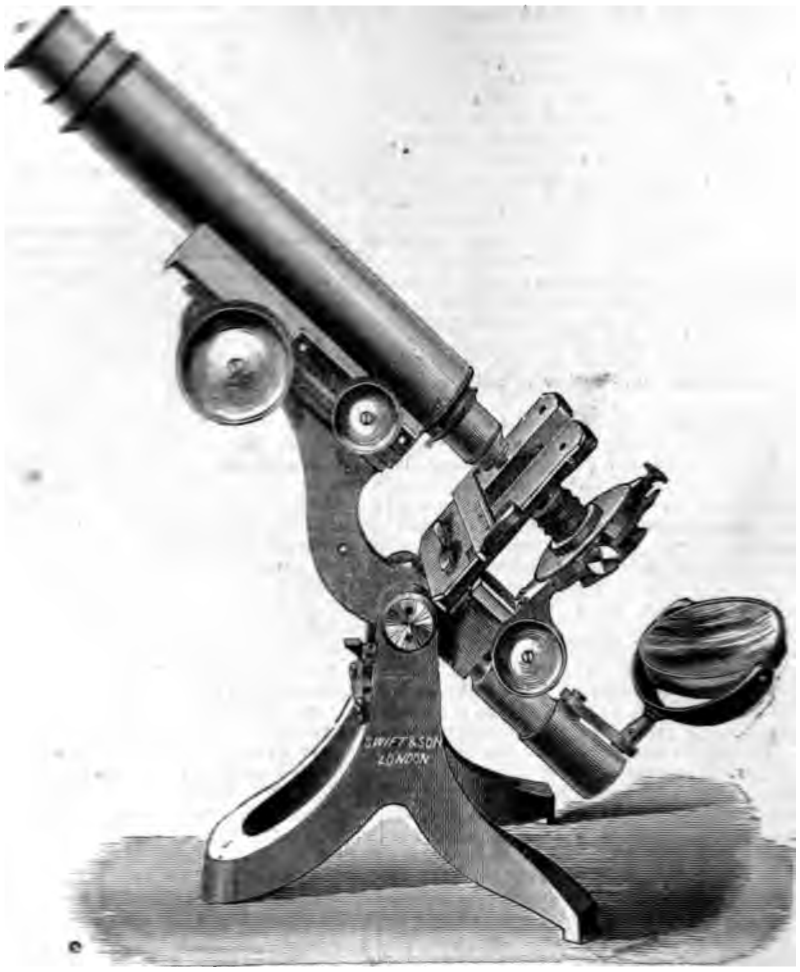
In his fifth lecture, Prof. Dewar spoke of Newton's sublime demonstration, that the laws of motion extend not only to all the heavenly bodies, but also to molecular changes with which chemistry is concerned. But they had not yet done with the workers before Newton. Of the alchemists belonging to the thirteenth century Raymond Lully was reputed to have transmuted 20,000 tons of lead into gold, a tradition needing no comment, save that a quarter rose noble passing as one of Lully's was afterwards exhibited, which Prof. Roberts, of the Royal Mint, guaranteed as the purest gold. On the same high authority it was believed to have originally existed as an alloy of a far larger mass of silver, which having been separated by the action of nitric acid, the virgin gold was left behind. In this connection an experiment prepared by Prof. Roberts was performed, showing the newly-discovered peculiarity of gold, that after cooling down from a fiery fluid into a dark solid it suddenly flashed forth into more that it former brightness Another alchemist in the same century actually mounted the papal throne—namely, John XXI. Roger Bacon was the third great light of that age. Paracelsus, to whom the healing art owed so much, came two or three centuries later. It was he who first introduced the use of the metal antimony in medicine. A series of slides photographed from authentic sources were passed through the lantern and thrown on the screen to illustrate the apparatus and experiments of the alchemists. First came a rudely drawn furnace for the distillation of wood, then, amidst dragons and other mystical [illegible] experiments, notably by the decomposition and recomposition of water. The wire carried the [illegible] sparks, keeping red hot and even emitting light under water so long as the fire was discharged from the battery. By means of this new agency Davy split caustic soda, till then deemed an elementary body, into the metal sodium and the gas oxygen, following up this discovery by adding the [illegible] alkaline metals to the short list of those known to the ancients. This was an immense achievement, but it was a far greater that he had invented and set to work so [illegible] and powerful an engine of chemical analysis. Mention was made, also, of Mr. Justice Grove's [illegible] experiment for resolving steam into its constituent gases, hydrogen and oxygen, by passing it over the white hot spirals of platinum wire. The remainder of the lecture was devoted to analysis by the spectroscope, profusely illustrated by experiments.

TOOTHING A NICKING SAW.

THE nicking or cutting off saw in the machine shop is a necessary tool for many purposes, but, unlike knurling tools, it is not to be found in [illegible] in the supply stores. The usual method of producing a saw is to chisel it out of a piece of cast steel of the required thickness, or to [illegible] from a bar, drill the centre for an arbor, file or [illegible] the periphery, and, after truing it, file the teeth.

A better way to form the teeth is to make and [illegible] one hob of eight threads to the inch [illegible] threads to the inch, hobs made like those [illegible] thread chasers. But for forming the [illegible] the hob should be cut to a single angle tooth, [illegible] having an acute angle on one side—the [illegible] a right handed thread, the other [illegible] right angled to the axis of the hob. A [illegible] of the selection of the tooth is got from [illegible] milling tool or the circular saw [illegible]

[illegible] hob suspended between the centres [illegible] can be cut or toothed by a very [illegible]. The drilled and turned saw blank [illegible] in the ordinary [illegible] having a stud on which the blank is [illegible] by means of a nut and washer, but so that [illegible] [illegible]



NELSON'S STUDENTS' MICROSCOPE.*

OUR Figure shows a medium-size microscope, constructed by Messrs. Swift and Son, embodying some suggestions of Mr. E. M. Nelson, with special reference to histological research with high powers when only a moderate outlay is allowable.

The principal point of novelty is that the front of the stage is cut away so that the position of the substage, with the diaphragms, condenser, &c., may be readily seen from above the stage, and the diaphragms rapidly changed: also permitting the finger to be placed on the upper edge of the slide for safety in focussing with high powers. Amongst other additions, it may be noted that finders are applied on the stage by which the position of an object may be recorded without the use of mechanical movements, the graduations for the vertical movement being on the stage-plate, and those for the lateral movement on the sliding-bar carrying the object. The optical body divides in two for portability. The eyepieces are fitted with different lengths of tubing, so that the 10in. length is maintained with each from the diaphragm to the nose-piece, as with Powell and Lealand's microscopes. Mr. Nelson's centring substage with lateral swinging diaphragm-carrier is also applied.

CHEMICAL EXPERIMENTS IN THE LANTERN.*

THERE is one class of experiments which has hardly received all the attention it deserves—namely, chemical experiments performed in the lantern, an image being thrown on to the screen. Not only are such experiments attractive in themselves, but they may be put to real service in showing on a large scale many of the [illegible] which the [illegible] of photography [illegible]. [illegible]

[illegible]

[illegible]

polished surfaces of these strips should also be rubbed down to give them a ground surface which will afford them a stronger hold. The cell may then be put together by warming the glass and applying marine glue, with the aid of a heated piece of iron, —an old file, for instance, or, in the absence of anything better, than useful domestic implement, the kitchen poker. One disadvantage of marine glue, however is that the heat from the lantern, if it is in for a long time, may cause it to leak. Another good way of joining the glass, and one which requires less skill, is to cement it with bichromated gelatine and expose to light; if this plan be adopted, it is advisable to paint the cemented edges, inside and outside, with sealing-wax varnish or gold size applied with a camel-hair pencil. Gold size may itself be used to cement the glass; but, except for microscope cells, we do not care for this. A very good form of cell may be made by mixing two pieces of glass in wooden frame the size of an ordinary carrier but thicker, these two pieces of glass being separated by a piece of rubber tube, or, better still, a strip of solid rubber such as is used for [illegible] bent round to form the bottom and sides; the glass plates are placed sufficiently near together to squeeze the rubber and make a watertight [illegible]. [illegible]

[illegible]

[illegible]

a solution of some dye, such as turmeric or indigo; the effects of acids and alkalies on solutions of blue and red litmus, &c., &c. So many experiments will naturally occur to the mind of the reader that it is needless for us to enumerate more. One of the best things we have seen demonstrated in this way, though it is hardly within the province of the photographer, was the electrolysis of a substance, a solution of chloride of copper being used to which a small quantity of a solution of indigo in sulphuric acid was added. As the chlorine gas was evolved in little bubbles at the positive pole, the indigo was rapidly bleached, the experiment being rendered very striking by dividing the cells into two parts with a little roll of blotting paper, a terminal being placed in each of the two divisions of the cell.

AN IMPROVED CARRIER FOR LANTERN SLIDES.*

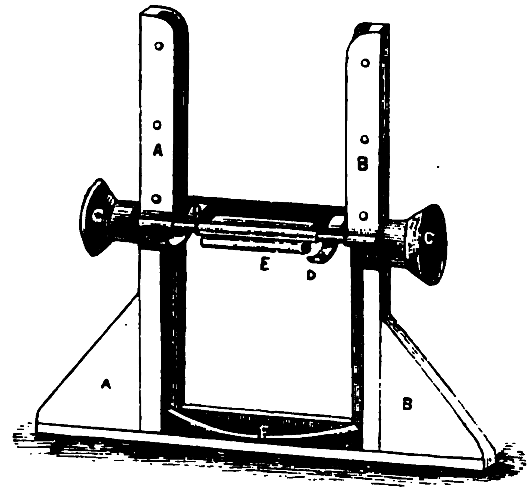
NATURE again looks frowningly upon all that pertains to the photographic art. The landscape is bare, and the camera is rarely to be seen outside the studio; the lens of which, even there, wears its cap over its eye perhaps a little too long for the professional photographer. Nevertheless we have little cause to grumble. The light of science shines even brighter in these dark December days; at least, as far as photography is concerned, we can well afford the sun its few weeks' retirement in the regions of mist and cloudland, so familiar to the Sons of "Caledonia stern and wild." But the foot-prints of the tripod are still upon the mountains' brow. Though the click of the instantaneous shutter is heard no more, there must be mental as well as photographic impressions amongst us of where we have been with the camera, and the question naturally arises, How shall we impart to our fellows a share of that pleasure which the modern appliances of our art are capable of bestowing upon all true lovers of Nature? The answer is, by means of the lantern—the optical lantern, or Sciopticon, as the modern instrument is now called, for which every photograph of interest should be produced in the form of a slide, if there is a desire on the part of the artist to see it to the best advantage.

The management of the lantern at public exhibitions does not seem to get that share of attention which ought to be bestowed upon it, and Photographic Societies should endeavour to take the lead in this direction. It is with the desire of stimulating ours to greater activity that I venture to approach you on the subject.

The lantern slide carrier may sound to some of your ears as a very unimportant part of the lantern outfit, yet to my mind it is the very back-bone of a successful entertainment. Mr. Chadwick, who has done so much to simplify lantern manipulations, has overcome, to a certain extent, the difficulty of exhibiting slides of various sizes, and we all join with him in the lament that slide-makers cannot agree as to the size most convenient for this purpose. Here is a matter to decide at the proposed International Photographic Congress at Brussels. A universal size of slide would do much to advance the interests of photography, and remove a load of anxiety from the mind of the lantern conductor. We would then be in a better position to exchange slides with other nations, and be sure of exhibiting them without any special arrangement in the form of our carriers.

Mr. Chadwick's improved carrier, as you are aware, is simple and effective enough when two lanterns are used, but for the mere purposes of exhibiting a series of photographic views there is no need of two lanterns, unless it be for the purpose of *effect*, and that is no small matter in a lantern entertainment. To see a picture come on the screen in its proper place and remain there quietly till the lecturer has passed his remarks upon it, and to pass as quietly away, is a pleasure we seldom enjoy under present circumstances. When a single lantern is used we are accustomed to see the pictures pass along the screen in regular, and sometimes irregular, succession, with an ugly streak of black between each, caused, you are aware, by the binding of the two glasses and the round or cushion-shaped mask between them. Why this has been so long the form of mounting slides is difficult to understand: it is much better to leave out the mask, and with the picture close up to the edge, bind only the top and bottom of the slide; and if the push-along process of exhibiting them be adopted, we have something more approaching a panoramic effect, and the eye will not be so painfully impressed with what in reality appears more prominent than the picture itself, namely, its mask and binding. This, with the single lantern, will be found a practical way of getting over the difficulty when slides of various sizes are to be exhibited; indeed there need be no limit to the length of the landscape slide, though for portraits the mask is indispensable. A universal size of slide, after all, would be the most acceptable.

Fig. 1.



I shall now describe my carrier and the mode of using it. The only difficulty in the way of its being immediately adopted is that a special arrangement is necessary to be made with that part of the lantern which bears the lens. The improved Sciopticon requires no alteration except in the hood which shades the light between the condenser and the objective. After seeing the carrier at work, you will find it requires no great amount of mechanical skill to effect the desired alteration, and to introduce what I venture to hope you will consider an important improvement in lantern slides carriers. The following sketch will give some idea of the shape and mechanical arrangement of the carrier in its improved form

A A and B B Fig. 1 is the frame, which may be made of either wood or metal. C C is a spindle which passes from side to side of the frame, terminating at each end with a suitable thumb-screw, by which it is turned in the act of changing the slide. D D are two metal plates passed through the above spindle, which act as levers in pushing away the slide. E may be called a self-acting balance lever, the form and action of which will be better seen in Fig 2. F is a spring to counteract the force of the falling slide, upon which the successful working of the carrier much depends, in adjusting which be careful to give it a slight turn inwards, so that the slide on falling may not be forced outwards. Fig. 2 is a full-size section of the principal part of the carrier as seen from the side. A is the spindle; B the self-acting balance lever, which is simply a plate of metal bent round the spindle in the form represented, the round black part of which is filled with lead, thus causing the lever to press against the slide C, and hold it in position till forced away by the spindle levers in the act of changing the slide.

In using the carrier drop a slide in at the top of the frame at A and B, Fig. 1, till it rests on the spring F. That being exhibited on the screen, drop another slide in at the top as before, while the spindle levers are lying in a horizontal position, thus preventing the top slide from coming in contact with the bottom one. The lecturer having finished his description of the view on the screen, gives the signal, while you give the thumb-screw C a slight turn, and, in a flash, the scene is changed.

If I have made the description plain enough, you will perceive the slide on being expelled from the carrier falls forward upon a cushion or pad, from which it is removed during the description of the succeeding slide, and so on till the close of the lecture.

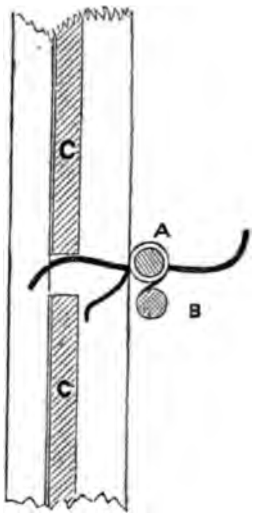
I ought to say that to some the idea of exposing the slides in this way is not new. My carrier, in its original form, was shown to some of the members of this society five years ago. Since then there was something similar spoken of in the journals, though I have sought in vain for a description. This, and the desire to introduce an improvement in our lantern exhibitions, is the only apology I have to make in bringing before you a lantern innovation.

---

[*] By J. McKean. A paper read before the Edinburgh Photographic Society.

A free railway exists in Oakland, California, a town on the opposite side of the bay from San Francisco. The Central Pacific Company desired to pass through it, and the principal street offered the best route; but the people of Oakland only consented on condition that they should have free passage over this section of the line, which is the case, no fares being demanded.

Fig. 2.



SCIENTIFIC SOCIETIES.

ROYAL ASTRONOMICAL SOCIETY.

THE January meeting was held at the Society's Rooms at Burlington House on Friday, the 11th inst.; Mr. W. H. M. Christie, Astronomer Royal, in the chair.

William Henry Davies, 55, Great Newton-street, Liverpool; Edward H. Nightingale, M.A., 3, Park-row, Albert-gate, S.W.; Cuthbert E. Peek, B.A., Wimbledon House, Wimbledon; and the Rev. W. H. K. Soames, M.A., Chesterton-road, Cambridge, were duly elected Fellows of the Society.

Mr. Glaisher read a paper by Mr. Pratt, of Brighton, on "The Belts of Saturn." He had observed the narrow belt described by Mr. Ranyard at the last meeting on several occasions since October, and believed that it was not a new feature. The paper was accompanied by a photograph of a drawing of Saturn made in September, 1874, in which a similar belt in the northern hemisphere of Saturn was shown. Mr. Pratt described the belt in the southern hemisphere, which he identified as corresponding to Mr. Ranyard's belt as of a Vandyke brown colour, consisting of a string of small clouds situated in latitude about 10° south. He had observed a similar belt there for some time.

Mr. Ranyard said: Since the last meeting I have heard from Mr. Denning, who has kindly sent me a drawing of Saturn, showing a narrow belt similar to the one I described at the last meeting. Like Mr. Pratt, he seems to have seen it last year. He agrees with me in placing it in latitute about 15° or 20° south, and makes it also adjacent to the southern cloud-cap. Mr. Denning has seen this belt within the last few days. I find, also, that Mr. Ward, of Belfast, has seen a similar belt, so that there can be little doubt about its existence. I have not seen it broken up into a string of clouds, as it is drawn by Mr. Pratt; but I suspected loops or notches on the edge of the belt, something like the loops or notches seen on the belts of Jupiter, but not so distinct: these were smaller notches. Mr. Green tells me that he has seen these notches, and has no doubt about them. It appeared to me that the belt was a bluish-brown, rather than a reddish-brown, but I do not attach much importance to estimates of such faint tints.

Lieut.-Colonel Herschel: There can be no doubt about the existence of this belt. My brother tells me that he has seen it, and that his daughter, who is a child of only 12 or 14 years of age, saw it when it was pointed out to her.

Mr. Knobel: The belt drawn by Mr. Pratt is almost identical with the belt or string of clouds shown by Trouvelot in his well-known drawing published in the *Proceedings* of the American Academy.

Captain Noble: If I understand rightly, Mr. Pratt's belt, which is in the northern hemisphere, would now be almost in contact with, or hidden by, the ring. Its edge might, perhaps, just be seen above the crape-ring, where it crosses the planet. We are looking now at the other side of the ring from that shown in Mr. Pratt's drawing made in 1874. I have seen, in contact with the ring this year, something which I took to be the shadow of the ring on the planet, but I find that the shadow could not have been seen from the Earth at the time, so I think that it may have been Mr. Pratt's northern belt, or possibly Mr. Ranyard's belt, though I think that would have been higher up.

Mr. Green made a drawing on the blackboard to illustrate the appearances he had seen on the ball

SCIENTIFIC NEWS.

OBSERVATIONS of Comet Pons-Brooks, as it is now called, have been made in nearly all parts from which intelligence has been received, and sufficient data have no doubt been obtained to determine the period with almost complete accuracy. In the *Comptes Rendus* of the 31st ult., M. Perrotin, of Nice, gives a record of his observations up to the 24th of December, when the nucleus of the comet was equal in brightness to a star of the 5th magnitude. A tail nearly two degrees long was visible to the naked eye, and was surrounded by a nebulosity about 7′ in diameter. M. Trépied, at Algiers, has examined the comet with the spectroscope, and found the spectrum to consist of two bands in the green of different degrees of brilliancy, the more refrangible having a greater degree of brilliancy than the other; a third band, very faint, was seen in the blue. He finds these bands to be practically identical with those found in the spectrum of an alcohol flame.

M. Cornu, the distinguished French physicist, has communicated to the Academy of Sciences, Paris, a note of his observations of the rare phenomenon of a white rainbow, or Cercle d'Ulloa. The phenomenon was observed between nine and ten, the sun having risen in the midst of level banks of cloud. A thick hoar frost covered the ground, and a light fog thinly veiled the sky, which, however, was clear towards the zenith. Opposite the sun there appeared a great white arc or rainbow, without a trace of colour. M. Cornu gives the apparent altitude of the highest part of the bow as 23° 26′; the apparent span 80°, while the height of the sun was about 17° 24′. He compares the appearance to that of smoke rings made with phosphoretted hydrogen.

Mr. Latimer Clark has issued (Spons) a little manual of the Transit Instrument as used for obtaining correct time, which, with his tables, and the instrument itself, will enable any one to obtain absolutely correct time with a less error than one second.

No. 25 of the *Mineralogical Magazine* contains a paper by W. H. Hudleston, M.A., the president, on a recent hypothesis with respect to the Diamond Rock of South Africa; another by Mr. J. H. Collins, on the "Minerals of the Rio Tinto Mines," the bulk of the part being, however, taken up by Prof. Heddle's continuation of the "Geognosy of Scotland."

At a recent meeting of the Glasgow Philosophical Society, Sir W. Thomson read a paper on "Measurement of Electric Currents and Potential," in which he spoke of the importance to practical electricians of such instruments, and stated that at the Vienna Exhibition he had been greatly impressed by the want of instruments to give definite and accurate measurements. He does not think this want will long remain unfilled, and proceeded to explain two instruments of his own invention—viz., a graded current meter and a graded potential meter. In future he will express the rate of conductivity in "mhos," a term which he thinks will be useful in describing the reciprocal of ohms.

A series of experiments on the effect of various gases in reducing metals from solutions has been made by Dr. G. Gore, F.R.S. He thinks the process for reducing metals might be useful in physical experiments, and believes that the metals found in the fissure veins of the earth's crust may have been produced by the gaseous hydrocarbons derived from organic sources.

The thirty-seventh annual general meeting of the Institution of Mechanical Engineers will be held on Thursday, the 24th, and Friday, the 25th, at 25, Great George-street, Westminster.

According to the Patent Office rules, drawings are to be prepared on Imperial paper, within a border line of 27in. by 19in., or 19in. by 12in., leaving a margin of ½in. all round. Unless some mistake has been made with reference to the margin, the paper will have to be trimmed, for whole sheets of Imperial drawing paper are 30in. by 22in, and half-sheets are therefore 22in. by 15in., which it will be seen leave a margin of 1½in.

Another matter connected with the Patent Office and the new Act is that notwithstanding the clear provisions of section 45, subsection 3, the Office refuses to accept renewal fees by instalments on patents granted prior to the commencement of the Act, or at least on those for which the fees of £50 and £100 have become payable recently.

A salesman in Covent Garden market recently advertised for a few pounds of ripe strawberries, stating that he had a special order, and could get £5 per pound!

M. Debray has communicated to the Academy of Sciences some new facts relating to the liquefaction of nitrogen. Oxygen has been liquefied by high pressure, and when that is suddenly withdrawn the lowering of the temperature is so great that crystals of solid oxygen appear, and nitrogen in contact with liquid oxygen becomes liquid too.

A conversazione was held at the Public Hall, Harrow-on-the Hill, on the evenings of the 9th and 10th inst, under the auspices of the Young Men's Society of the town. Some interesting examples of railway signalling were shown by one of the heads of departments in the L. and N. W. Railway; Mr. St. John Gunn exhibited some experiments in electricity; and a good collection of model engines, kindly lent by Mr. R. A. Lee, of 76, High Holborn, attracted considerable attention.

The Prince's Theatre in Coventry-street, which is opened to-day, has been fitted with arrangements for electric lighting by Messrs. Strode and Co., of Osnaburgh-street. The auditorium will be lit by four electroliers of twenty lights, each suspended from ceiling to the different tiers by electric brackets and pendants. The foyers, grand stairs, corridors, &c., and also the float light for the stage, are fitted with the electric light. The current will be generated by one of Siemens's S. D. dynamo machines, driven by a 12 h.p. gas engine, the current being stored by a Faure-Sellon-Volckmar accumulator of 55 cells. The lights are all ingeniously fitted for gas as well as the electric light, in case of casual failure of the latter.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 81, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

THE LATE J. H. DALLMEYER—"RECONCILIATION" AND RUBBISH—RECENT SUNSETS—THE LIGHT OF OTHER DAYS—THEORY OF THE SUN'S MOTION—THERMOMETER BOX—FLUORESCENCE.

[22236.]—IT was with most sincere regret that I observed the announcement of the death of one of the most scientific opticians in England—I mean Mr. J. H. Dallmeyer—at the comparatively early age of 53. Few men combined the amount of mathematical knowledge that he possessed, with his intimate practical acquaintance with the mechanical operations of his profession. As thoroughly familiar with theoretical optics as he was with practical lens grinding, he had at once the mind to conceive and the mechanical skill to produce instruments which his untimely death will now render more precious than ever. I remember, when I was a very young man, the late Andrew Ross saying to me, in speaking of Dallmeyer, "Sir, if he lives, he will be the first object-glass maker England has yet seen." There are many who will think that he did survive long enough to justify this prediction of his great forerunner. Great as were his attainments, no more modest and unassuming a man ever lived, and the loss of John Henry Dallmeyer is emphatically one to practical science.

I was very sorry, too, although in a different way, and for a totally different reason, to see that Dr. Kinns (who is, I am afraid, a Fellow of the Royal Astronomical Society—albeit he was "declined with thanks" at the Geological) had been attempting, in a lecture in the library of Canterbury Cathedral, to show that the first two or three chapters of Genesis are *scientifically* accurate. I have, for my sins, waded through Dr. Kinns's book ("Moses and Geology") upon this subject, and a more wonderful hash of authorities, from the worthiest to the most worthless, and astonishing muddle of their conclusions, I never came across. The mischief done by these pseudo-"reconciliations" is incalculable. Ignorant people accept them *pro tempore;* but finding out their rottenness with increasing knowledge, arrive, in a large proportion of cases, at the fallacious conclusion that, because such attempts to show that Genesis narrates physical facts are all rubbish, everything narrated in the mass of writings of which that book forms the exordium, must be equally valueless. It is men like Dr. Kinns who furnish the Atheist and the Freethinker with his most powerful weapons: enabling him to say to the frequenters of "Halls of Science" and the like: "If a theological system requires bolstering up by such easily-refuted nonsense as this, what sane man need waste any time on it?" It would be utterly contemptible, were it not pitiable, to see a Kinns getting up and talking about all the theories of evolution being swept aside, at a time when the grave has only just closed over Darwin! Verily this affords a saddening example of the manner in which Religion is wounded in the house of her friends. (Since writing these lines I have seen Mr. Carruthers's crushing attack on Dr. Kinns's rubbish in a morning newspaper. It is as true as it is pungent. I could hardly give it higher praise.)

The ideas of "B. R." (letter 22194, p. 384) appear to be—if he will forgive me for saying so—just the least thought vague. The peculiarity in the recent sunsets really consisted, not in the depth of their colouring, gorgeous as that was, but in the appearance and persistence of the crimson afterglow long after the sun had descended below the horizon. "B. R.'s" notion that anyone has tried to associate the ordinary red, orange, greenish, and steel-blue hues of sunset with meteoric dust is a fallacious one. What has been contended, with a very considerable show of reason, is that impalpable meteoric dust at a great altitude would reflect the red light produced by the passage of the sun's rays through vapour-laden air after the sun was at a considerable distance beneath the horizon. In our ordinary sunsets the warm colours are chiefly produced by transmitted light, the cold ones by reflected light, and the neutral tints by both combined. So much for your correspondent's concluding paragraph. With reference to his first one, meteoric dust in greater or less quantities is always suspended in the air; but it is, as I have just previously intimated, in the form of an impalpable powder. It is brought down by every shower of rain; but, of course, this does not entangle it and preserve it for examination as snow does. It does not become incandescent, because it offers little or no resistance to the air. In the case of shooting stars, they may weigh from half an ounce upwards, and entering our atmosphere with a velocity of between 20 and 30 miles a second, are dissipated into vapour by the mere friction. Doubtless, we derive our main supply of meteoric dust from this very source, although it may also exist in space in an impalpable form too.

"J. H. C." (letter 22202, p. 386) has only to carry out his conception a little further, and imagine himself to be travelling away from the Earth at a sufficient rate of speed, to see how all terrestrial occurrences would be inverted. Trains would seem to leave their destination and arrive at their starting places, balls travel into the muzzles of guns, men regrade from old age to infancy, and so on.

It is not very easy to answer a query put in the form of 52592 (p. 395); but, perhaps, it may help "P." to understand what the President of the Royal Astronomical Society meant by the words he quotes, if he will reflect, that in the Solar theory we adopt a certain mean motion of the Sun in longitude, which we call a Mean Solar Day. It is, however, quite evident that every time we change our adopted value of the Sun's mean motion we change the length of our adopted day. I am expressing no opinion here as to whether Mr. Stone's idea is a correct one or not; I am simply trying to put it into slightly different words. His conclusions are endorsed by that most eminent geodesist and astronomer, General Tennant; while Professors Adams and Cayley contend that while *a* change in the unit of mean solar time must result from the substitution of Le Verrier's tables for Bessel's formula, such change only amounts to the $\frac{1}{385}$th part of that which is alleged to have taken place by the Radcliffe Observer.* I must, though, caution "P." that the whole discussion is of a highly technical character, and one which scarcely admits of being put in a popular form.

I grieve to say that "Agricultor" pays me wholly undeserved compliment in query 52606 (395) in his supposition that I use "a properly-co structed box" for my thermometers; if by be means one of the orthodox thermometer stands, with louvres, &c. My wooden thermometer frame is placed against the north wall of my observatory, with a slight interval between them to enable the air to circulate. It has a deep pent-roof and wings at the ends, so that the sun can never shine on the instruments, even at the end of June. Otherwise, the frame is freely open to the north. Doubtless, though, many of our more essentially meteorological brother-readers will give him a description of the stand now so generally employed.

Mr. Harcourt (query [illegible], p. [illegible]) should get some fresh seeds of the thorn-apple (Datura stramonium), and pour over them rather more strong spirits of wine than will suffice to cover them, letting them macerate in this for some time. Paper written on with this tincture shows the writing most beautifully phosphorescent in the violet and ultra-violet rays of the spectrum. I have often experimented on this by projecting a spectrum from an ordinary prism on to paper prepared in this way, without even darkening the room; but of course, the effect is more striking if the experiment be performed in a dark chamber. Or, if the room be darkened, and only rays passing through deep blue or violet glass be suffered to enter it, the writing shines brightly out under such illumination. Has your correspondent ever tried an infusion of horse-chestnut bark, made by pouring hot water over it? This solution is yellow by transmitted light, but of a beautiful blue by the violet rays which it disperses. Red sanders wood, too, if infused for some time, yields a slightly-coloured solution. To this we must add a little liquid ammonia, and it will then look brownish by transmitted light, and a strong blue by that dispersed.

A Fellow of the Royal Astronomical Society.

COMPANIONS OF SIRIUS—CASTOR A—D.

[illegible].—Certain minute companions to Sirius have been suspected on more than one occasion, but the evidence of their actual existence is not very strong. The accompanying diagram and brief account of these objects may, however, be of some use to those desirous of searching for these minute points of light. The recognised *comites* are three in number, and are lettered B, C, and D in the diagram, where their approximate positions are given for 1884·0; a cross shows the place of Sirius in 1862·0, the irregularities in the p.m. being of course neglected. B, the well-known companion, was discovered by Mr. Alvan G. Clark, on January 31st, 1862, and is the only one at present known to be physically connected with Sirius. It is not a difficult object with a moderate aperture, provided the air is steady, and has been seen in these latitudes with a 5in. refractor. It has been suspected of variability, but probably without sufficient reason. It is now rapidly approaching its primary, and in a few years will scarcely be visible with the largest telescopes, the calculated distance in 1890·1 being only [illegible]. C was discovered by Marth, with Mr. Lassell's 4ft. reflector at Malta, 1865, January [illegible]. The following are the principal measures of this star:—

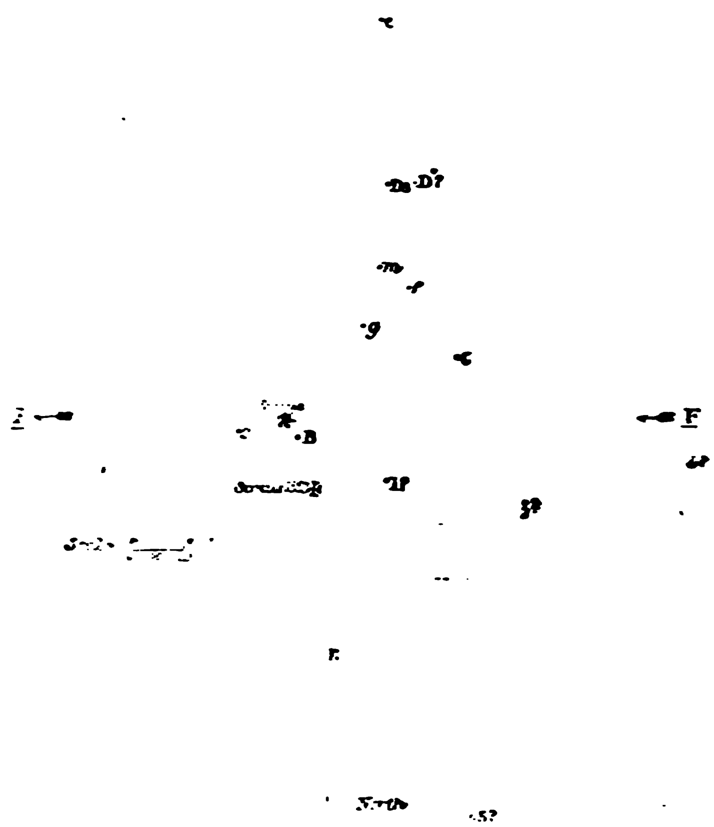
	°	″	
Marth	[illegible]	—	1865·[illegible] ([illegible]).
Hal	[illegible]	[illegible]	1877·[illegible] ([illegible]).
[illegible]	[illegible]	[illegible]	1877·[illegible] ([illegible]).
[illegible]	[illegible]	[illegible]	1878·21 ([illegible]).

Hal. rates it about 13 mag. in S.'s scale. Dr. Wentworth Erck has seen it with his 7in. Clark. D is one of Goldschmidt's companions (No. 3), and is an easy object with 6in. aperture. For this we have—

	°	″	
Marth	[illegible]	[illegible] —	1865·[illegible] ([illegible]).
Se.	[illegible]	[illegible]	1865·[illegible] ([illegible]).
MacGeorge	[illegible]	[illegible]	187[illegible] ([illegible]).
[illegible]	[illegible]	[illegible]	187[illegible] ([illegible]).
[illegible]	[illegible]	[illegible]	187[illegible] ([illegible]).
[illegible]	[illegible]	[illegible]	188[illegible] ([illegible]).

Se.'s measure is printed [illegible] in the second series of measures, and has been supposed to refer to some companion seen only on the occasion of his measure; but I have very little doubt that it should be as given above. The changes in C and D are due, of course, to the p.m. of Sirius.

Shortly after Alvan Clark's discovery, Goldschmidt announced, in a letter to Prof. Peters, that he had succeeded in detecting six new stars near Sirius, only one of which (his No. 3, D.) has ever been recognised by any other observer since. His account of his observations will be found in *Comptes Rendus* LVI., p. [illegible]; *Ast. Nach.*, Vol. LX.; *Monthly Notices* XXIII., pp. [illegible], 243, &c. The note on p. [illegible] of Vol. XXIII. of the *Monthly Notices* is said to be "translated, and the woodcut extracted from No. [illegible] of *Les Mondes* (the weekly scientific journal edited, in place of the *Cosmos*, by M. l'Abbé Moigno)"; and the woodcut given in Vol. I. of the *Astron. Register*, p. [illegible], is also said to have been copied from the same publication. I have been unable to find any woodcut in *Les Mondes*, or any allusion to Goldschmidt's observations other than the note on page 130, and the *Cosmos* likewise only has the excerpt from the *Comptes Rendus*. As there are some slight differences between the two woodcuts in the *Notices* and *Register*, I have preferred to employ that given in the latter publication; and for the details of the observations I have used Goldschmidt's communication in the *Comptes Rendus*, the translation on page 131 of Vol. XXIII. of the *Notices*, and Goldschmidt's letter on p. 243 of the same volume. Some of the details of the observations are rather difficult of comprehension, probably owing to typographical errors. Goldschmidt expresses his astonishment on finding that Clark's *comes*, which he was able to see at intervals with the telescope he used (a 4·2in. refractor) was not the only one, and that there were several others in the immediate neighbourhood of Sirius, at distances varying from 15″ to 1′ of arc. He says, "Mes moyens restreints d'observation ne me permettaient pas de mesurer les distances de ces points lumineux immergés dans l'éblouissante lumière de Sirius," but that No. 1, "sans aucune doute un compagnon," is situated to the south of Clark's *comes* and has a position angle of 95°–97°. It is visible at intervals, and appears a little farther off than A. C.'s. (Goldschmidt assigns both letters and numbers to the stars in his communication in the *Comptes Rendus*: but I have omitted the letters, as they differ from those given in the diagram in *Monthly Notices*, and if retained would only cause confusion). No. 2 is an almost imperceptible point, situated on a line drawn through Sirius and Clark's comes. No. 3 (D) is to the east of Sirius and No. 1, on the same parallel as the latter, distance from Sirius 3·60s. to 3·80s. in R.A. No. 4 has a position angle of 170° [?], and No. 5 of 25° to 30°, "et sont distantes de Sirius par rapport au compagnon No. 1." There is also a star about 10″ to the east of No. 3 D; this I have marked D. One thing is pretty evident from Goldschmidt's description and drawing, and that is, that he has greatly underestimated the distances of the stars seen, or supposed to have been seen, by him. The stars are arranged by him in order of distance, and, as all the companions are said to be within 1′, No. 3 (D) would seem to be about 45″ or 50″ from Sirius: the actual distance in 1865 being about 119″. I have placed Goldschmidt's stars in about the positions they would seem to occupy from his description and diagram, but as the places are naturally very vague, I have added a "?" to the Nos. No. 2 is said to be in a line with Sirius and Clark's *comes*, and the pos. angle should therefore have been about 85° ± in 1862, but the position of Clark's star and No. 2 in both the diagram in the *Monthly Notices* and that in the *Register* is nearer 55°. If my surmise as to the distance of Goldschmidt's companions is correct, it is easy to see why Nos. 2, 4, and 5 have been overlooked by later observers; at the same time I am very far from saying that I believe in the actual existence of any such stars. It is not generally known that Goldschmidt found two close companions (of which he gives a diagram) to Procyon, "si près de Procyon," he says, "que l'on peut à peine les voir séparées ou détachées de la grande"; but I should be very much inclined to put these at least down to an optical illusion. We know, from the case of γ Libræ, for instance, that Goldschmidt largely underestimated the distance of faint companions, and in the case of very minute points near the overpowering blaze of Sirius, the natural tendency to do so would be greatly increased. The only other observations of faint stars near Sirius which demand investigation are those of the observers with the Melbourne reflector. They will be found in the *Transactions* of the Royal Society of Victoria, X. pp. 69, 70, and 128—130. Eight diagrams are given; but the observations are not of a very satisfactory character. The star β is placed from the sketches of December 23rd, 1869, February 2nd, 1871, and February 23rd, 1872. Its actual existence seems more than doubtful; but I have assumed that its p.m. is the same as that of Sirius. ε, the most distant, was first seen by Mr. MacGeorge (who made nearly all the observations) on December 9th, 1870, and on several subsequent occasions since; ζ and [illegible] were seen on Feby. 2nd, 3rd, and 4th, 1871, and Feby. 23rd, 1872; α apparently only on Feby. 23rd, 1872, K, which is called a "group," on Feby. 2nd and 3rd, 1871, and Feby. 23rd, 1872. They do not appear to have been seen in the great American refractors, or with Lassell's reflectors.

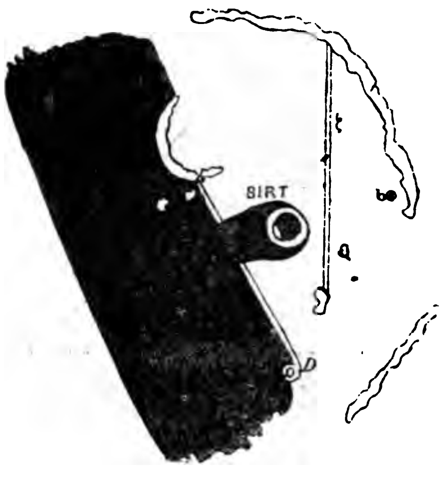


Castor A—D. In the ENGLISH MECHANIC for July 14th, 1882, p. 426, I referred to a very distant companion to Castor measured by H. and So., the distance being 197·114″ (misprinted 177·114″ in my letter No. [illegible]). I have recently found that there is a curious error in the distance of this star in H. and So. The distance is entered on p. 107 of their work, and in other places where it is quoted, as 3′ 17·114″. The actual value is 3′ 37·114″—i.e., that corresponding to 902·98 parts of the micrometer of the 7ft. equatorial. The measure, therefore, stands 224·25° : 217·114″ : 1823·12 (1 night). The date of the second measure of the angle of A—C is given in H. and So. as 1822, Feby. 19th; it should be, as I find on consulting the original MSS., 1823, Feby. 19th. It is well known that C probably forms a ternary system with Castor; it is very unlikely that D is also physically connected, but it is desirable that its present angle and distance should be put on record.

Jany. 7th, 1884. **H. S.**

SELENOGRAPHICAL—BIRT—MESSALA —HORBOX.

[illegible].—In the *Astronomical Register* for December, Mr. Gwyn Elger mentions the clefts [illegible] and [illegible] east of Birt, the former of which is a tolerably easy object, while the latter is very rarely to be seen. He relates the only recent records of its existence which he has met with. I was fortunate enough to see it on Nov. 24, 1880, when it and [illegible] appeared as one continuous cleft, which commenced on the north at the hill shown by Mr. Neison, and passed Birt at a little distance instead of bending up to its wall as on Mr. Neison's map, and sloping somewhat to the east, it extended quite up to the ridges which almost inclose Birt and Straight Wall on the east and south. This is the only occasion on which I have seen both clefts, but ϕ has been visible at other times, on one of which I thought it passed through this hill, though I could not trace it beyond. I send my sketch of Nov. 24, 1880. Two



of the row of hills between Straight Wall and Thebit are visible on it.

May I take this opportunity of telling Mr. Elger also with regard to the semicircular ridge on the floor of Messala mentioned by him in the *Astro. Register* for November, that in Dec., 1881, there was a corresponding semicircular ridge outside the wall of Messala, the two forming a complete shallow ring divided in half by the wall? I am supposing that the ridge seen by him is that half of the ring which is within Messala on its floor. I have a sketch, but perhaps this description is sufficient.

On Jan. 6, at 11h. 45m., I was able when the clouds broke to obtain a few glimpses and a sketch of the crater in Horrox. The mist never wholly cleared away, and the moon was getting rather low, so that vision was not very good, but I plainly saw in the position Mr. Gaudibert indicates a good-sized circular black spot, which, whatever it really is, had the appearance of being a deep black hole. It strongly reminded me of Hyginus N. There was a very little shadow under the south-west wall of Horrox, from which the spot was quite separated. Whether it was also separated from the wall nearest to it, or whether it extended into shadow there, I could not distinguish; neither could I distinguish the ridges on the floor of Horrox. On Jan. 7, at 6 p.m., I made another sketch. The spot was still visible, but was less black and rather elongated southward towards the ridge, the shadow of which it joined. Both ridges were visible.

On both nights, and especially Jan. 7, the spot was a very conspicuous object. **M.A.**

AFTERGLOW—JUPITER—SATURN—MARS.

[22239.]—I HAVE seen no mention of one fact with regard to the remarkable light and colour lately seen in the sky. During the continuous cloudy and foggy weather of which we have now had so much, there has often been a strong rose-coloured glow upon the clouds in the W. and N.W., extending half-way to the zenith, and visible as late as 6 and 7 o'clock. On the 2nd of January it was remarkably strong, and had it not been for its perfect steadiness, one would have set it down at ence to be an aurora. A slight rain was falling at the time. I have repeatedly discerned it during the last few weeks, more or less strongly visible. Seen like this on a cloudy sky, it surely must be an atmospheric effect, and not due to meteors. Is the aurora ever seen as a perfectly steady glow, projected on an entirely cloudy sky? The delicate sea-green colour which has been seen in the sunset effects recently, and which has been mentioned as unusual, has been noticed by me sometimes in remarkably beautiful sunrises for many years past. It is rare, but far more rare at sunset than at sunrise. I have remarked it more often in the sunrises of autumn than any others. It generally appears as a narrow band of clear sky bordered above, and sometimes below also, by dark clouds. It is one of the most delicate tints that it is possible to see.

With regard to Jupiter and Saturn, the points I have noticed are that the definition of Saturn and the outline of the ball and rings is always much sharper and more distinct than the definition of Jupiter, the latter appearing soft and woolly at the edge, giving one the idea of looking at a thick atmosphere. Secondly, that Saturn bears a higher power than Jupiter, which is very noticeable. This follows naturally, I should suppose, from its sharper outline and definition. Thirdly, that fine mist of a certain kind improves the definition of the belts of Jupiter by diminishing the glare.

The difference in colour of the ball of Saturn and the rings is always striking with anything like a good night, the ball being almost a deep yellow and the rings a pearly white. The difference in colour of the outer and inner ring is always to be seen also, the inner being the whitest and the outer more dusky with a somewhat stratified appearance, as if composed of numerous narrow rings. The outline of Mars is never sharp to me, and it is the most difficult of the three to observe; but this is probably partly due to the fact that it requires a larger telescope than the other two planets. One other atmospheric point I have noticed during the last two or three months: that the temperature has varied so rapidly and so greatly, sometimes as much as 10° in one night—e.g., on Dec. 17 up to midnight, it was 30°, and by 3 a.m. it had reached 40°. For more than a week now the temperature, even through the night, has been 50° and higher, quite as mild as many summer nights. I do not remember so high a temperature as this through the night at this time of year ever before. **M. A.**

[22240.]—WHILST discussing the very curious phenomenon of the chromatic sunsets which have engaged the attention of our correspondents for the past month, nobody seems to have noticed how strangely non-actinic the light has become. Mine is but amateur experience; yet on trying photography I found twice the time required which I would judge necessary to insure an image under normal circumstances at this season of year, and on mentioning the matter to a professional I found my experience coincides with his. Viewing those sunsets and sunrises through a rainband spectroscope-we are struck with the prominence of those lines (telluric) which indicate aqueous vapour in the atmosphere. Possibly we shall have another wet, stormy, and cold year, which in this country causes infertility in the soil and want in the harvest.

E. B. Fennessy.

THE PLANETOIDAL RING.

[22241.]—THE contributor of the excellent article on the Progress of Astronomy throughout the Year (page 375) appears to have a great contempt for the study of the Planetoidal ring, with the exception of those few planetoids which may be utilised in the calculation of the solar parallax. From this view I venture to differ. It certainly would be unsatisfactory not to have an approximate knowledge of the scale on which the solar system is formed; but this we already possess. The ratios of the various planetary distances to that of the earth are indeed needed to the greatest possible accuracy, as the basis of the perturbational theory; but the doubtful correction to the extent, perhaps, of one-twentieth of a second of the solar parallax at a great expenditure of time and money, is to be deprecated if astronomical labour is to be saved rather than the expenditure of the same upon the Cis-Jovian The *Berliner Jahrbuch* recommends strict attention not merely to the asteroids which approach the earth, but also, besides others, to those such as Hilda, Ismene, Hecuba, Gerda, Urda, Sibylla, &c., which approach Jupiter nearly.

The latter group has been sometimes proposed as useful for determining with great accuracy the mass of Jupiter; but this would only be required for the more accurate calculation of perturbations, and this brings me to the main point I have in view, which is that the ring merits more attention—on its own account, and not as subsidiary to any other body in the system—than anything else in the solar system of the three classes of bodies, major planets, planetoids, and comets. As a test of the theory of gravity and a means of discovery of residual phenomena, the planetoids are incomparably the best. This arises from the circumstance that the perturbations of most of them are greater than those even of Saturn; in fact, those planetoids which come very near to Jupiter are disturbed by that body almost as much as are the comets, and then, owing to the extreme smallness of their disc, they can be observed with much greater accuracy than the major planets, not to speak of the comets. This is a point of great importance. The late astronomer, Le Verrier, suggested that the discrepancies between his theory of Jupiter and Saturn and observations, might be owing to the sensible discs of those bodies.

It may be said that the theory of gravity requires no further confirmation; but is it not, *à priori*, improbable that the exact law should be so simple as we suppose? In most, if not all cases, such simple expressions as at first seem to satisfy a series of facts, are found, upon a more profound study, and the observation of fresh facts, to be but a first approximation to the law. Are we sure, for instance, that the law of attraction is that it is proportional to the product of the masses of the attracting and attracted bodies (I am not speaking simply of the acceleration).

An attempt has been made to explain the existence and phenomena of comet's tails by the hypothesis that the sun acts very differently upon different kinds of matter, which is really only another way of saying that the action between two bodies is not proportional to their masses, or that the law of gravity is not always true—in some cases, not even a first approximation.

Personally, I do not think this explanation of cometic tails will hold water; but that is another question.

We may say that the law appears to hold so far as the sun and major planets are concerned, taking into account their mutual actions. But many of the planetoids would be an infinitely severer test. We have further considerations connected with the past and future, or evolution, of the solar system, on which a profound study of the ring seems likely to throw a great light. It appears probable that all the planets, and most, if not all of the satellites, were in their embryonic stage a ring of fragments.

We can no longer conclude the planetary interspaces to be a vacuum, were it only for the meteoric dust.

Now, in consequence of the smallness of their size, consequently of their masses and discs, the effect of a medium may be demonstrated upon the planetoids, when it would be utterly impossible as regards the major planets, although from such a determination we may be able to see the effect upon the major planets during a very long time.

Further, it would seem to me, at least, a matter of great interest, by a comparison of calculation and observation, to ascertain the fact of collision between the visible planetoids and the smaller. Such determinations would require the exhibition of the absolute perturbations of most, if not all, the asteroids, which, with present methods, would be a very great labour. But the aiming at this ideal might tend to improve the method very materially hitherto employed.

Whatever may be the direct utility of determination of the solar parallax by means of observations of some of the minor planets, or of the transits of Venus, indirectly they are, no doubt, the means of introducing great improvements in our instrumental appliances, which is in itself no small advantage.

It was, I believe, the opinion of Le Verrier that no nearer approximation to the solar parallax than we now possess could be attained with any degree of certainty, except, in the course of time, by means of gravitational method, which, again, would require, to be certain, a profound examination of the nature of the residual phenomena which may exist after the elimination of the action of the ordinary law of gravity as hitherto postulated.

I have read that the second opposition of Hilda has been observed towards the end of 1879, but without details. Perhaps some of your correspondents may be able to say whether this is true, and how many oppositions have been observed, if any, since that period. **W. C. E.**

ELECTRIC MOTOR FOR LAUNCH MODEL.

[22242.]—THE "Electric Motor for Model Launch" (see letter 22200) is one of M. Trouvé's, consisting of a simple Siemens armature revolving between the prolonged poles of another electro-magnet; section looks something like small capital I pivoted in its centre in the upper part of a large U. The poles of the armature are reversed every half-revolution by a commutator on its spindle, so that both parts are always being attracted or repelled from both poles of the magnet cell. The current passes round the magnet and through the armature; the battery is a bichromate of potash. For full description see page 16 of Dary's "La Navigation Electrique," published by Baudry, 15 Rue des Saints Pères, Paris, price about 1s. 6d.; or page 107 Urquhart's "Electro-Motors." Du Moncel and Geraldy's "L'Electricité comme Force Motrice" and Hospitalier's book also contain interesting accounts. All these works may be consulted freely at the Patent Office Library, Southampton-buildings, Holborn; but if desired, I will go into detail on a future occasion.

Horloger.

[22243.]—"A BIG BAIRN" (letter 22200, p. 385) asked for information which, without being a captious critic, I beg leave to say letter 22231, p. 410, does not afford. "A Big Bairn" correctly described what he saw: a model boat, with a battery aboard, and fitted with an electro-motor. If he will turn to issue of Jan. 7, 1881, p. 415, he will find a full description of the motor (Trouvé's), and an illustration, showing it in position, as in the model in question, which I have seen some dozens of times. There would be very little difficulty in making a motor like this, and the cost would be trifling. There is also further information on this motor on p. 479, Jan. 21, 1881; also in the "Development of the Pacinotti Ring," fully illustrated at p. 51, March 25, same year. For practical information about the fitting of armature, see p. 41 of present volume. New readers of the "E. M.

KEY CHARACTERISTICS IN MUSIC.

[22248.]—N. E. Child (22225) is wrong. The [illegible] harmonium is a patent article. The specification says the keyboard may consist of one row of digitals and reeds, or of more than one row. If of one row only—the least complex form—the scale is more than its master, for the scale is not in it. Key characteristics must therefore be cut. This is all I have to say. **George Templeton.**

BEE-KEEPING.

[illegible]—What has become of all our practical bee-masters? Some time ago we had very complete instructions how to make hives and get the bees into them; but none of their signatures have appeared in answer to the query on bee-food. This I much regret, as I think the present is the most suitable time to look up matters which may be of service in the coming spring and summer. I find it rather a ticklish job making "candy." I made some a little while ago, but as it did not seem to be clear of powdered sugar when dry, I added a few drops of vinegar to the next batch. Somehow this will not boil dry and hard, although it is quite clear, and makes excellent butter-scotch, almost as good as the celebrated Doncaster production. But I do not like its appearance, as I am afraid it will become sticky inside the hive. Should anything at all be added to the melted sugar to make it boil clear and hard—if so, what?

Next comes the query, Will bees exist on this or flour cake without some sort of liquid? I find those fed on it often seeking water when they have a chance to get out. I am afraid the present mild weather will eventually be fatal to many stocks, as I find their food consumption is much greater than in severe winters, when they are compelled to keep quiet. A mild winter is often the precursor of a severe frosty spring, and if this happens, very many hives will require feeding to keep them alive.

What is really meant by chilling the brood—that is, what temperature is fatal, and how long must they be exposed to it? Suppose a hive is opened and examined in early spring, if the larva are unsealed, will this exposure be injurious? Also, if they are sealed over, will they hatch out if the combs have been exposed in the air any length of time. These and other kindred matters I hope to see dealt with by some practical bee-keeper, and a few hints on management and preparation for the coming season would be very useful to many.

Orderic Vital.

THE NEW PATENT RULES.

[illegible]—[illegible] say in a recent issue that rule [illegible] will [illegible] draughtsmen. I quite agree with you. I have had over [illegible] years' experience of making drawings of machinery and apparatus of almost every class, and now I must in my old age confess that I am incompetent to comprehend the meaning of the [illegible] rule. If I have a round invention I might be able to compress it within a circle of [illegible] diameter, or a square invention might be shown in a square of [illegible] by [illegible]in., a long invention by a parallelogram of [illegible] by [illegible]in., and a very long narrow invention by a strip [illegible]in. long by [illegible]in. broad. Each of these inventions represents a space of [illegible] square inches, but the question is, would the controller accept any of these inventions as complying with the rule? Neither of the above cases cover more than the prescribed "[illegible] square inches." Again many valuable inventions are comprehended in the mixture of certain substances in definite proportions—what [illegible] drawing will be required for inventions of that class? I am afraid that draughtsmen will not only be [illegible] puzzled" but driven to their wits' end to represent some inventions within a space of "[illegible] square inches." I think it is a very great pity that the Board of Works did not procure the assistance of a [illegible] to advise them [illegible] he would have explained the difference between "[illegible] square inches" and [illegible] square [illegible]

Inventor.

TRICYCLES.

[illegible]—I have read with much interest the letters which have appeared during the last few weeks in your valuable paper upon tricycles, with [illegible]

[illegible] limbs. This hard slogging up hill appears to me to be caused through each treadle in its turn requiring so much pressure putting upon it to force the machine along until the opposite treadle is in a position to receive the strain, and which, in my humble opinion, is nothing short of donkey work.

On the flat ground it is quite different, because the speed one is travelling at (even if it be ever so slow) throws the one crank after the other ready each time it is wanted, except when starting, and then if the crank-shaft and chain-wheel are tight together, and are in direct line with the leg, you must go on "Shanks's pony" a pace or so to put the matter right, or turn the driving-wheel with your hand.

As far as the coil spring goes, I do not see why it should not be of service; but I am inclined to think that if a machine were made so that as the one crank had lost its power—say, by the left foot—the one for the right should be ready to take up the work at once, without having to wait for the driving-wheel to travel over 18in., or 20in. of ground before the work begins. This would bring the machine similar to a locomotive, which can start in any position, the pressure being on round the entire circle traversed by the cranks, and would, in my opinion, assist in hill-climbing better than any other power. As I am not acquainted with many makes of these articles, I should be glad if some of your correspondents could favour me with a sketch of such a machine, if such is in the market at the present time; or the name of it would do, if you allow such remarks to be made. I shall be able to find the maker if the name is given.

Rag.

LIGHT AND HEAT.

([illegible] from p. 411.)

[illegible]—It will be observed that the cause of light vibrations is here attributed to sudden changes in the density of the luminiferous ether. Let these be effected with sufficient velocity, and, considering the infinitely elastic and expansible character of the substance, here is not only a good, but also a sufficient explanation of the luminous vibrations. The greater the velocity of the expansion and contraction of the ether, the greater the brilliancy of the light produced.

There exists an intimate connection between heat and light. Both are forms or modes of motion, and the motion of light is capable of producing the motion of heat and transferring it from one body to another, as, for instance, from the sun to the earth. There is, however, this essential difference between them, that whilst light is the vibrating motion of an imponderable, infinitely elastic substance pervading space, heat is a motion of the ultimate particles of ponderable matter, and is, therefore, unlike light, only conveyed as the motion of heat from one body to another, through the actual contact of material particles existing between the two bodies. The conduction of heat is therefore a transmission of molecular motion from one body to another, and as different bodies possess different powers of transmitting heat, the speed and distance of its propagation vary accordingly.

Heat can be generated in various ways. By mechanical means, as friction, compression, and percussion, by chemical combination and combustion, and by solar radiation, which is the most intense source of all.

The generation of heat by friction, compression, and percussion is a conversion of mechanical energy, and requires for its production, and produces by its disappearance, an amount of force equal to [illegible] foot-pounds for every thermal degree Fahr. As heat and mechanical motion are mutually convertible, no matter the source of heat, this mechanical equivalent of heat obtained by raising a pound of water 1° Fahr. in temperature, is generally adopted in all calculations of heat and work.

Chemical combinations, whether slow or rapid, are usually attended with heat, the same quantity being produced in both cases; although when evolved slowly, as by the oxidation of metals in the air, the heat produced is imperceptible. Combustion is a rapid chemical combination accompanied by the evolution of both light and heat, although the temperature does not depend upon the luminosity, as great heat can be obtained without light, this depending upon whether swift condensation accompanies the combination. In ordinary combustion, such as where the carbon and hydrogen of coal or oil combine with the oxygen of the air to form the products carbonic acid gas and water, and especially when a portion of the carbon condenses at a high temperature into the solid form, light more or less brilliant accompanies the chemical combination, depending upon the velocity of the condensation.

Of all sources of heat, that of the sun is the most intense, although there are no means of estimating it except by the luminosity of the solar surface. This has been calculated to exceed more than [illegible] times the brilliancy of the limelight, the heat of which is estimated at [illegible] C. Of the nature and effects of a solar heat [illegible] times greater than this, [illegible] In this supposi- [illegible] But the speed [illegible] the h.p. times and allow it to fall upon the seat upon which it was intended to rest. Experience quickly proved that a certain amount of elasticity was very necessary, and that perfect rigidity of foundation is most objectionable: stone blocks and cast-iron sleepers have therefore been discarded in favour of the usual wooden cross sleeper.

Clement E. Stretton.

Saxe Coburg-street, Leicester,
Jan. 8th, 1884.

CHEAP LATHES—SLIDE-RESTS.

[22257.]—PERMIT me to thank the gentleman that has supplied the articles on "How to Make a Cheap Lathe." They have been very interesting indeed.

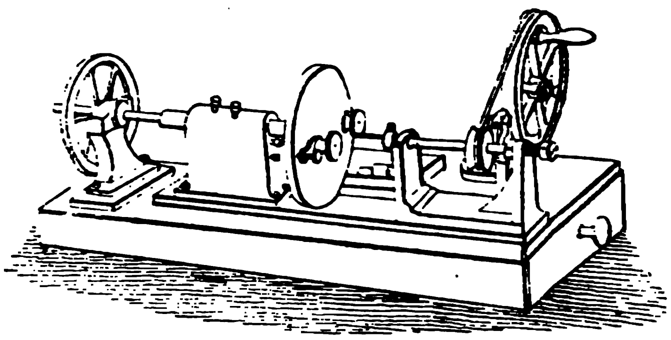
Perhaps our friend would favour us with sketches and necessary information how to make a compound slide-rest for, say, a 4in. or 4½in. screw-cutting lathe. I am sure it would be interesting to many beside myself.

Lill.

HORIZONTAL DRILL.

[22258.]—FOR the benefit of my brother readers, I have sent our Editor a photograph of a small horizontal drilling machine which I designed and constructed myself. It is made for drilling holes from about $\frac{3}{32}$in. down to the smallest size ever required by any amateur. The instrument stands on a piece of maghogany 12in. by 6 by ¾, the height of the centre is 1¾in., and the diameter of the faceplate, to which the work is clamped for drilling, is 3in.

If any amateur wishes to construct one of these instruments for himself, I shall have great pleasure in giving the dimensions through the pages of our



MECHANIC, and will also lend the patterns if so desired, provided postage is paid both ways.

Dundalk. **Thos. J. O'Connor.**

LATHE MATTERS.

[illegible]—THE top bearing slip of the front slide-lathe is, in my opinion, better made of the blunt V form, rather than the common shape for horizontal slides. Of course, the chamfered part may slope towards the bed, instead of away from it as in the diagram. It would then resemble the ordinary V with the sharp edge planed away considerably. Whichever method is used, the V should be cut down so as to get as broad a bearing surface as possible. It is then less liable to get knocked or chipped out of truth, and as a further safeguard against this contingency, the top chamfer seems better on the outer than the inner side of the slip. A semicircular section to this part would seem better suited than any other, as it offers no sharp edges to accidental blows: but I presume it would be far more difficult to fit accurately.

I do not like the plan of canting over the centres, if it can be possibly avoided. Freedom from tremor seems most likely to be attained when the line of fixture passes vertically through the line of centres.

I am very glad Mr. Carre has noticed the plan, and hope it will be taken up by practical machinists. Our pattern-maker has shown how it may be conveniently modelled. The articles by "J. H." are among the most valuable that have ever appeared in this journal. Everything is so clearly planned and dimensioned, that no one can have any difficulty in following the writer's instructions. It is not everyone who knows all about a thing, that can impart his knowledge to others; but fortunately we have in "J. H." one who is both an expert master and an accomplished teacher. In pattern-making there is much that is pleasant and profitable to the amateur who can finish his own. It is a matter requiring neatness and accuracy in workmanship, and needs a steady hand and a careful eye. With such instructions as those given by "J. H." no one can be puzzled to know how a thing is made; but the measurements are equally as important as the sketches, for there is a certain proportion of parts which gives a thing neatness and stability. The desideratum is to give just so much metal as is needed, and no more: any needless strength must be an incumbrance. This is just the point where the experienced eye can render useful services: hence, I regard the papers and diagrams on lathe construction as far superior to many previous ones of a somewhat similar character, and I trust your obliging contributor will in future papers enter upon more complex lathes and machine tools, not forgetting also the steam-engine.

Orderic Vital.

LEGAL REPLIES.

[22260.]—BILL ON DEMAND (52583).—This query has been fully answered by "C.," but answered according to the special rules of the Scotch law, which may mislead other readers. In England a bill drawn payable "on demand," &c., "bearing interest," would carry interest at the rate of 5 per cent. per annum, in the absence of any other agreed rate, from the date of the bill itself. The Statute of Limitation begins to run from the date of a bill made payable "on demand," and therefore no action could be supported upon the bill more than six years after this date. But if interest were paid upon the bill, this would keep the right of action alive, and an action could be brought for the whole sum due within six years from the last payment of such interest.

PROVING A WILL (52600).—This, too, has been answered; but I think it is only fair that a few words of warning, and to prevent disappointment, should be added to "Collector's" very *rosy* view of the easy way in which a will *is proved*, and which, indeed, is only true when the will is in every respect formally complete. If the attestation clause is quite accurate, and there is no flaw in the executor's oath, the business is simple enough. But it frequently happens that the will requiring proof is very informal indeed, and then, however polite the Inland Revenue authorities may be, they cannot show an executor how to get through the business. A lawyer must be consulted to say if the will is worth anything at all, and to draw the necessary affidavits for the attesting witnesses to prove signature and attestation.

DETAINING LUGGAGE, &C. (52724).—I never heard of the presumed right of a tradesman to stop a customer's trunk for an unpaid account for grocery goods sold. The idea is simply preposterous, and can only have arisen owing to the great confusion that exists in many people's minds as to the legal right of lien. A vendor can retain the goods he sells until the price is paid, if he chooses, but this is the full extent of his lien: and neither he nor anyone else can seize them afterwards without a lawful process of execution or distress. Workmen and the like have a right of lien upon articles they repair until paid: but they cannot retake them if once credit be given. The claim mentioned by the querist is quite unfounded.

Fred. Wetherfield, Solicitor.

2, Gresham-buildings, Guildhall, E.C.

REPLIES TO QUERIES.

*** In their answers, Correspondents are respectfully requested [illegible] the number and the title of the query asked.

[illegible] —**Learning the Zither.**—This instrument is [illegible] difficult to learn; but may be [illegible] much difficulty by taking a few [illegible] master. Don't trouble yourself [illegible] books, they are more trouble than [illegible] I made great progress in two [illegible] but six lessons, and now can play [illegible]—M[illegible].

[illegible] —**Brush Dynamo.**—As I expected, [illegible] and commutator are entirely wrong. If you will carefully consider the action of the [illegible], you will observe that each coil is short-circuited for about five-sixths of a revolution, so that you are not getting one quarter of the real power of your machine. If you want to use your present commutator, you must connect your machine up as a [illegible], as I explained at first, and I have no doubt you will get much better results. A proper Brush commutator for your machine would consist of three brass rings, each cut into two halves and insulated from each other, and the two ends of opposite coils joined, and their beginnings connected one to each half of a ring.—W. H. E., Coventry.

[illegible] —**The Cheapest Food.**—May I call Mr M[illegible]'s attention to the fact that his reply on p. 411 is no answer to my question as to what is the composition of the foods he has now twice advertised gratuitously? No one disputes, so far as I know, that they are wholesome or delicious; but they are not cheap, for Scotch oatmeal and crushed wheat, while quite as delicious, are very much less in price. It would, I think, be absurd if any one asked for the cheapest drink, to suggest Bass's bitter, which might fairly be described as wholesome and delicious, but scarcely cheap to the man who wants at least half a gallon during the day. As I have [illegible] to the drink, can any one suggest anything better than the infusion of oatmeal, treacle beer, or [illegible] beer for those who literally earn their living by the sweat of their brows and require large quantities of drink in the course of a hard day's work?—S. R.

[illegible] **Watch Jobbing.**—English turns can be bought, large size 8s. 6d., 9s. 6d., and 10s. 6d. each, small pivot turns with steel rest and two centres, 4s. 6d. for watch work only. Swiss can be bought with eight centres, six fitted ready for use, and steel rest [illegible]. I think the Swiss most useful for clock and watch work combined. Respecting the spring hook, first see that your spring is the proper length required for the barrel, make a small hole a little from the end, a round hole preferable, chamfer the inner side to receive the burr caused in riveting. [illegible] your steel, square or round, and fit to the eye of your barrel easily, then file the seat for spring as shown in Fig. 1. Be careful to make a

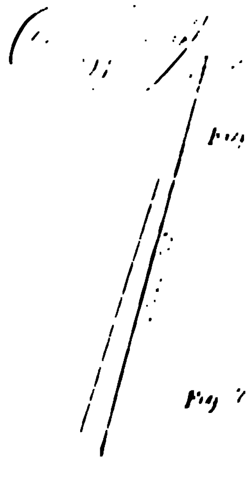


Fig 1

Fig 2

[illegible] then tap the [illegible] a notch with a screwhead file near the point, file the sides a little with that file, so that a small eye may take hold which should be very near the end in this case, and filed thin. Screw in your hook (be sure it stands right way for the spring) until the hook is visible inside, cut it off and file up, polish, &c. A bow screw will sometimes answer the purpose, as in Fig. 2.—MODEL.

[52338.]—**Holtz Machine.**—I am glad to see in Mr. Holmes's answer that the discrepancies of "Another S." have been pointed out independently of myself. I quite endorse his opinions. I am afraid "Another S." is quick at jumping at conclusions. The plates I mentioned in Mr. Spottiswoode's great machine, weighed about ¾lb. at the utmost, and cost 4s. 6d. per lb., so I don't quite see how they would mount up to £2 10s. each. Again, "Another S." is rather caustic with me for mentioning that "although I went a walk in the country after working in the same room in which the machine was running, my clothes still retained a powerful smell of ozone." I merely mentioned this to give an idea of the vast quantity generated. He must also have a comparatively small experience with ozone, as any physiologist or physicist will tell him that ¼ a per cent. of it in air will be sufficient to make the eyes smart and the lungs to be seriously affected for some hours after inhalation for an hour, or even less.—P. WARD.

[52354.]—**Gelatine Transparencies (U.Q.)**—If "Glatton" has met with any special difficulty, and will say what it is, I shall be happy to try and help him.—W. ROBINSON, JUN.

[52362.]—**Engineering (U.Q.)**—Since the diameter of the screw = 2·756in., the circumference of it will be 2·756 × 3·1416 = 8·6582in. nearly, and the pitch of the screw = 5in. The above dimensions will be the base and perpendicular of a right-angled triangle, and the hypotenuse will be the thread of the screw. The angle between the base and the thread can be readily found with a protractor; or by logarithms we have—

$$\begin{aligned} \text{Log. } 2{\cdot}756 &= 0{\cdot}4402792 \\ 3{\cdot}1416 &= 0{\cdot}4971509 \\ \text{Log. } 0{\cdot}9374301 &= 8{\cdot}6582 \text{ nearly.} \end{aligned}$$

And if A be the angle between the thread and the base, we have—

$$\text{Tan A} = \frac{5}{8{\cdot}6582}$$

$$\begin{aligned} \text{Log. } 5 &= 0{\cdot}6989700 \\ \text{Log. } 8{\cdot}6582 &= 0{\cdot}9374301 \\ \text{Log. tan. A} &= \bar{1}{\cdot}76[illegible] = 29°\ 42'\ 21''. \end{aligned}$$

Since 1 horse-power = 33,000 units of work done in 1 minute, and the work done in 1 hour by the burning of 2lb. of coal = 33,000 × 60 units. But 1lb. of coal contains 12,000 units of heat; and the mechanical equivalent of 1 unit of heat = 772 units of work. Then the work done: the theoretical work : : 33,000 × 60 : 12,000 × 772 × 2: or—

$$\frac{\text{Actual work}}{\text{Theoretical work}} = \frac{33{,}000 \times 60}{12{,}000 \times 772 \times 2} = \frac{1}{9{\cdot}357}$$

or less than 1/9th of the heat contained in the coal is utilised. See Godwin's "Elements of Mechanics."—A. GRAY.

[52[illegible].]—**Photographs (U.Q.)**—First size with gelatine (about 20gr. to 1oz. water), then coat with [illegible] varnish.—W. ROBINSON, JUN.

[52[illegible].]—**Gem Lenses (U.Q.)**—1. It is usual to [illegible] screen with partitions in front of the sensitive plate, to prevent the images over-lapping: but, [illegible] deal depends upon what distances apart the lenses are placed. 2. Yes, just the thing if the lenses are good.—W. ROBINSON, JUN.

[52[illegible].]—**Chemical Problem (U.Q.)**—Will [illegible] state where he found this question?—[illegible], Elswick Science School.

[52[illegible].]—**Chemical Problem (U.Q.)**—The heat of combustion of methane is 213,530 units; [illegible] the elements constituting the gas were burnt [illegible] the total heat evolved would be [illegible] [illegible] units, and the difference between this and the amount actually yielded is obviously the amount absorbed in decomposing the gas [illegible] heat of formation of methane = [illegible] units.—WM. JOHN GREY.

[52[illegible].]—**Dynamo.**—This query can be answered by telling "W. W. W." that it depends on how he makes his dynamo. Most bearings can be felt with the hand; but if he is the least afraid he can use a paraffin candle to test the temperature of the metal. Most likely it will spoil the other lamp unless you shunt the current off or introduce a resistance equivalent to that of the lamps put out. [illegible] take all the work of a machine and [illegible] end in the destruction of its insulation and finally the melting of the copper.—S. P. T.

[52[illegible].]—**Legal.**—The coal goes with the land unless specially devised.—LIMB O' TH' LAW.

[52397.]—**Raising Water.**—This query is too indefinite. What is it the querist wants to know?—ESSAR.

[52405.]—**French Polishing.**—I suppose if Mr. Watkinson rubs his black paint or varnish down until he gets a smooth finish, and then French polishes, he will obtain what he desires. Surely he does not imagine that a carriage is covered with one coat of black paint and then varnished.—NUN. DOR.

[52408.]—**Skin Disease.**—A more simple (I do not presume to say a better) remedy for ringworm than that proposed by "Etheropathy," and one at hand in every mechanic's house, is thinly-made mustard. With the tip of a finger rub this semi-liquid, first outside the sore, then over it, always rubbing in a circle, and gently, and for a few seconds only. Repeat twice a day whilst necessary. For a child, it is a painful cure; but a grown-up person will not mind a few hours' smarting, and will find the cure rapid and effectual. Some people use ink in the same way.—H. O'B.

[52415.]—**Rushton's Self-acting Fountain.**—The description or the illustration is wrong. Try the arrangement on p. 260, or look in Nos. 45[illegible], 58[illegible], 801.—SENEX.

[52420.]—**White Fillings for the Teeth.**—The recipe must, I think, be correct, as I saw the same in the *Lancet*; but here is a good filling: Anhydrous phosphoric acid 12gr., pure caustic lime 13gr. Powder very fine. Mix and apply quickly, smoothing with a wetted finger.—NUN. DOR.

[52421.]—**Partnership.**—This querist should, it seems to me, consult a solicitor directly, and pay the usual fees.—LIMB O' TH' LAW.

[52423.]—**Paint for Machine Tools.**—Have your colours thoroughly well ground in turpentine, and then mix with oak or copal varnish.—E. C.

[52424.]—**Red Casting Wax.**—Add a little vermilion to ordinary wax, if that is what you mean.—E. C.

[52427.]—**Adhesive and Waterproof Paste.**—The German recipe is no doubt the cement made of casein; but it is doubtful whether the querist will find such a paste as he seems to want. Still, he ought, by looking up back volumes, to get an idea or two.—NUN. DOR.

[52428.]—**Battery.**—There is nothing so convenient of a small size as the chloride of silver cell; but Trouvé makes up small bichromates for use with his illuminated "doublets" or real rubies, &c., and also for the "animated" scarf pins and brooches. The chloride of silver cell is about the best you can have for a pocket medical coil.—NUN. DOR.

[52437.]—**Paper Ornaments and Toys.**—These are made of the pulp, I believe, and dried while in the moulds.—S. T.

[5244[illegible].]—**Paper Bricks.**—How would papier-maché do?—S. T.

[5245[illegible].]—**Belt Working off Pulley.**—I am sorry to inform W. Hoskens that I cannot explain to him how it is contrary to mechanical law that the belt works off the pulley at the sides which are nearest together. But the proof of the pudding is in the eating thereof. I would advise him to try it for himself, and I think he will see for himself that what I stated is correct. In fact, I have tried it many times, both on horizontal, diagonal, and vertical shafts, and invariably I have found what I stated to be correct.—FIRER, Dewsbury.

[524[illegible].]—**Belt working off Pulley.**—The blunder which is apparent in Mr. Hosken's reply is a very common one among people who reason that because a belt runs towards the highest point (viz., the centre) of an ordinary pulley with a convex rim whose shafts are parallel, it would do the same thing by running "up hill" when the shafts are not parallel. This is just where the "laff" comes in, though, friend Hosken, and is not "contrary to mechanical rule." Indeed, the only mechanical rule which has anything to do with belts running on pulleys unguided is the one quoted by me on pp. [illegible]. If you wish to "practice" yourself and "draw your own conclusions," you may do so by adopting the method recommended by "W. W.," pp. 550. Having made the string or straight edge correspond with two edges of one pulley, and one edge of the other, the shafts not being parallel, it will be observed that there is a space between the string and the remaining edge of pulley. This space represents the pitch of a screw-thread, and the belt will screw itself off, "down hill," at a rate equal to this pitch.—W. J.

[52[illegible].]—**Pianoforte Action.**—I should be very glad to help "G. B.", but I cannot quite understand what he means by "a hammer-rail action for a cottage piano with damper action combined." If by this he means an ordinary cottage action—which certainly would include a hammer-rail and damper action—he will find illustrated directions on page [illegible], Vol. XXVII. But, should he wish for an action with the dampers attached to the hammer-rail, such as are generally known as "under dampers," I will do my best to illustrate and describe for him a simple action of the kind.—W. H. Davies.

[52520.]—**American Organ, 16ft. Stop.**—Thanks to Mr. Fryer and "Organon" for opinion and advice on above. Mr. Fryer's specification entirely accords with my own idea, formed since the instrument in question was made. Would it not be better, however, to have both the 8ft. stops to run throughout? The organ my friend is making is for use in a chapel; therefore, the object is to obtain the maximum of power at the minimum of expense. The instrument I have made is also used in a large schoolroom; and were it not for the fact that the parties most concerned seem quite satisfied with it, I should be inclined to reconstruct it in F scale, with two sets of 8ft., one of 4ft.; solo set of 16ft.; sub-bass and super-octave coupler. I must protest against the instrument as it stands being dubbed a failure, as "Organon" sees fit to do. If it is a failure, then Mason and Hamlin's "Queen's Model" is a failure; for if the pitches marked on the stop knobs go for anything, it is identical for all practical purposes. Also in two-row harmoniums the second row is usually of 16ft. pitch. As regards the voicing, I did that myself, as I find I can produce as good a tone as any I have bought ready voiced, including some Munro reeds stated to be voiced in the company's factory. I find, however, a difference in the boards. A 1½ row I have just been voicing gave a good tone easily; whilst another I voiced some time ago could not be made to do so, although voiced in the same manner. I rather think the best makers throw aside these inferior boards, and only use those which, on trial, give good results. Why should not the tone of an American organ depend as much upon the quality of its soundboard as that of a fiddle does upon the quality and proportion of its various parts? Thanks to "Organon" for his idea of a two-manual; but if I made a two-manual, I should be inclined to have rather more than four rows.—J. E. Floyd.

[52543.]—**Pivot.**—It is evident from the query put by "B. W." that he is not a practical watchmaker, and as the repair he wishes information on is one requiring dexterity, he would do well to put the job into some one's hand who is experienced. The old balance must be removed by using suitable punches, to be obtained at any tool-house. The new balance riveted on by another kind of punch, after placing the banking-pin in front of the cylinder opening. With regard to the 'scape-wheel, the arms must be bent by gently tapping on a hollow stake: or perhaps the cylinder is too low.—W. H. Huddy.

[52548.]—**Wharf Crane.**—I am much obliged to Mr. W. Hosken for replying to my query on p. 393, but I fear my question was misunderstood. I do not want a crane, but wish to know how to calculate the weight a crane I have should lift with safety. It is a wharf crane of the simplest construction, worked by hand. I want to know what dimensions I saould take of this or any other crane to calculate its lifting capacity.—Vaga.

[52553.]—**Photographic.**—1. Although I hardly think the difference would be so great as stated, it must be borne in mind that, all things being equal, a single lens will work quicker than a doublet. 2. Yes. 3. Yes. 6in. focus I should consider best for general purposes.—W. Robinson, Jun.

[52558.]—**Food for Bees.**—It is kind of Mr. H. Wilson to try and supply "O." with what he requires, but not so to characterise his informant *re* "lemon-juice," as an "old woman," and the information "bosh," because it does not suit his views. I think most modern bee-keepers, and all modern bee-masters, will think the information that bees are partial to the flavour of "lemon, oil of mint, or butter," quite as open to H. Wilson's term "bosh"; for how are we to ascertain that they have any particular liking for any of these three flavours? Vinegar, or some kind of acid, is used in making syrup for bees, to prevent the sugar recrystallising. Oil of mint is used for scenting syrup when uniting bees, and butter is used for greasing tins or moulds, to pour candy in, so that it will easily leave the moulds when it is set. I fail to see why the fact of H. Wilson's boiling "1½ ton of sugar into various kinds of candy per month" can render his recipe any more genuine or difficult to beat. If he had boiled it all for bee candy, we should have thought him more of an authority. Is he a bee-keeper, I wonder?—J. I. S.

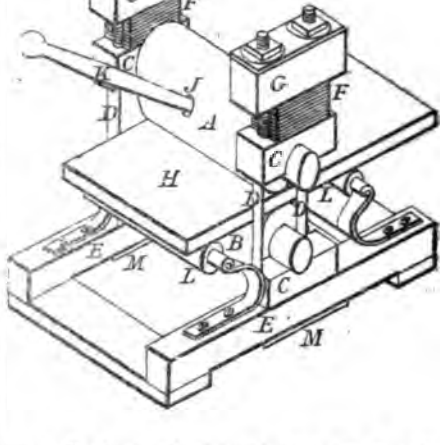
[52563.]—**Harmonium.**—"Fliegen" (p. 413) seems to misunderstand why I did not answer the previous questions put forth by him in a recent number of the "E. M." I do not imagine now a days that there are any very great trade secrets of any great value with regard to the construction of the harmonium, although great improvements have been made in harmoniums of late years, but the size for the holes at the top of the wind trunks is, certainly, no trade secret, as the querist imagines (p. 413), although it is of some little importance. The reason that I did not answer the questions put forth in the queries, was simply because I thought they were asked out of idle curiosity, and I must apologise to the querist if my presentiments are wrong. "Fliegen" will find that five holes of 1½in. diameter over each trunk will be a sufficient number, and with regard to the fixing of the escapements, if he can get a sight of the interior of a 2½ row harmonium, he will learn more than any number of words can teach him. There is more than one method employed in the fixing of the escapements, valves, &c., and any well-meant query from "Fliegen," or any other reader will, undoubtedly, receive my strict attention.—G. Fryer.

[52577.]—**Organette.**—I will write out the promised instructions on the making of an organette in a week or two; and as "T. J. P." (p. 413) has stated that the music which is sold is not the sort of music he wants, I shall be glad to know from him what kind of music he really does require, as both sacred and secular can be readily obtained from almost every respectable music shop at a very reasonable cost. If he will advertise his address, I will forward to him a list of tunes procurable for the organette, which comprises dance music, operatic music, sacred music, and overtures.—G. Fryer.

[52577.]—**Organette.**—As the original inventor, and first constructor of reed instruments automatically played by means of perforated strips of paper, or other material, I may be able to help your querist "T. J. P.," who inquires about the best scale to use. I may perhaps begin by explaining that there are two distinct ways in which the perforated strips are used: in one it acts directly as a valve to close and open the air passages, while in the other it acts as a "stencil" to a set of levers which open and close valves that cover the air-holes. To the former class belong the "Orguinette," the "Auriphone," the "Harmonette," &c.: to the latter belong the "Organette," the "Organina," and I think the "Orchestrionette." There are advantages and disadvantages in both classes, which I need not now go into, except to point out that, speaking generally, the openings (and consequently the strips) require to be much longer in the instruments where the paper acts directly as a valve than where it serves as a stencil. At first sight it would seem that by making a short perforation travel slowly over the air passage it would serve as well as a longer one; but I have found that this is apt to cause a droning, sluggish effect if carried out too far, and I think for promptness of speech in the reeds the "stencil" arrangement is the best. I also consider the mechanism of the "Organina" preferable to that of the "Organette," but this is merely my own opinion, and must go for what it is worth. Now for "scales." When I first commenced my experiments (nearly 25 years ago) I used a chromatic scale of 18 notes, but I afterwards found that it was better to have an imperfect scale extending over a greater compass. The scale of the "Organina" is the following:—B flat, C, D, E flat, E, F, F sharp, G, A flat, A, B flat, C, D, E flat, F, G, in which the B naturals, the C sharps, and the upper F sharp are omitted. This scale would, I think, be improved by the insertion of the B naturals, and the omission of the A flat, as though the F sharp provides for the key of G major, the B natural is much needed in this key, and the want of it, especially in chords, is decidedly felt. If "T. J. P." buys his music strips he must, of course, arrange his reeds to suit, but if he makes an instrument, and cuts out his strips for himself he can select what scale he pleases, and in that case the diatonic with the insertion of C sharp, F sharp, B flat and E flat, with (if he wants to omit any notes) the F naturals left out, will give a good variety of keys—viz., C, G, D, F and E flat—all major, with (to a certain extent) their relative minors—A. S. L.

[52580.]—**L. B. and S. C. Engines.**—Outside cylinders were never used on this line.—Machina.

[52582.]—**Copperplate Printing.**—The accompanying isometrical sketch will give "Copper" an idea of the press he wants, and is quite within the constructive powers of an ordinary amateur mechanic. The two rollers A and B are 9in. long and about 4½in. in diameter; the journals project 1¼in., and are fully 2in. in diameter. The upper roller must be of lignum vitæ, as the surface of any softer wood gets dented by the edges and corners of the copper plates passed through the press. The lower roller may be of any hard wood—beech, hornbeam, oak. The rollers revolve in bearings C C C C (one not seen in sketch), of beech or hornbeam. These bearings are made by boring a hole 2in. in diameter in two little blocks 4in. square and 1½in. thick, and then cutting them in halves, with the grain. The bearings are supported by four stout 16in. bolts D D D D, which pass through holes in their ends, and also through the bottom frame of the press E E. Upon the top of the upper bearing about fifty thicknesses of cardboard (old playing cards do very well) F F, to give some elasticity to the pressure. Above the cards come the caps G G, strengthened by iron plates ½in. thick on the upper side, and held down by square nuts and washers; between the rollers the plank H, of lignum vitæ, 9in. wide, 18in. or 20in. long, and 1in. thick is fitted. The



upper roller has a hole, J, bored, 3in. deep, in which a stout round iron lever K (the best end of a burnt-out kitchen poker will serve), by which the upper roller can be rotated, as a ship's windlass is by a handspike, through three-fourths of its circumference—say, 12in., giving the same travel to the plank H. Plates of iron M M, having square holes to take the square part of the bolts, D D, and, to prevent them being drawn into the wood, must be fitted under the pieces E E. All the holes for the bolts D D D D must be carefully bored the same distance apart, and close fits. The small rollers L L are to keep the plank H in a horizontal position. A better form of press would have a square iron axle to the upper roller A, but adds very much to the difficulty of construction. The inked plate is laid upon the plank H, with paper and two or three thicknesses of printer's blanket upon it, and by hauling on the lever K the plank, plate, paper, and blankets are drawn between the rollers and may be taken out on the other side, the next impression being taken the reverse way, or the roller may be returned so that the plate gets two squeezes. The rollers must be truly cylindrical, the faces of the plank truly parallel, and the pressure on each journal equal. I suppose "Copper" knows all the little dodges of inking and wiping, and cleaning the plate, as upon these depend, in a great measure, the value of the results.—Robinson Crusoe.

[52584.]—**Magic-Lantern Lamps.**—Your burner must be dirty. Take top off and thoroughly clean perforated work out, either by brushing with stiff brush or well washing in soda-water (do not boil it, as it turns it black), put together again and put into oven to dry. Use crystal oil or kerosene.—W. Jones, Viaduct-street, E.

[52585.]—**L. and S. W. R. Engines.**—The numbers of the 46 class on this line are: 46, 123, 130, 132, 133, 374, 375, 376, 378, and 379; 124 was originally one of this class, but has lately been rebuilt and furnished with an extra pair of wheels behind, and the vacuum brake apparatus. There are twelve of the 380 class; they are Nos. 380 to 391 inclusive. The numbers of the new bogie tank passenger engines with ten wheels are, I believe 416 to 427 inclusive.—Machina.

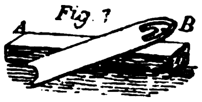
[52586.]—**L. and N. W. R. Engines.**—I am obliged to "H. N." for his reply, but it contains several errors. "L. and N. W. R. Engines" should be "L. B. and S. C. Engines"; whilst inside cylinders is evidently a mistake for outside. Again, there could have been double bearings to the driving-wheels only. The present 172 (Chichester) is not a coupled engine, but a 6ft. single (Craven) of the 194-200 class.—W. B. P.

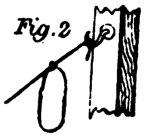
[52589.]—**Battery.**—You would want about 200 of the kind you mention: they are useless. The best kind can be made thus:—Outer cell, a rod of carbon; porous cell, zinc (amalgamated). Pack the outer cell with pieces of broken carbon, *not* dust, and fill up with a solution of—outer cell: bichrom. potassium, saturated solution, 1 part; sulphuric or muriatic acid, 2 parts. Inner cell—saturated solution of common salt. With 4 or 5 of these cells and a low-resistance incandescent lamp, you may obtain a light of about 4 or 5 candles. The duration would be about 5 or 6 hours continuously. The cells should be at least about 6in. high.—Cosmos.

[52593.]—**Clayey Soil.**—Your soil will be v suitable for potatoes, especially the kidney va ties, among them such well-known sorts as Y tain it will work properly, is not to be obtained any day in the week, and he is certainly possessed of an amount of common sense and judgment which he will have the common sense and judgment to expend on his own advancement in more profitable work. A man who buys a gas stove or gas fire without understanding the conditions under which it is to be used, is as likely to be suited as a man who buys a cart-horse for hunting purposes, and cannot understand the possibility of the cart-horse being a good one, if he cannot use it as a hunter.—THOS. FLETCHER.

[52633.]—**Gas Flames.**—The increase in light-giving power when two flames are caused to play on each other, is real; but the thing is nevertheless a "catch," as a single good burner, burning the same quantity of gas in one flame, will give quite as much light; in fact, under practical conditions, the single burner is much the best, as the compound burner, if turned low, is extremely liable to smoke. The larger the quantity of gas which can be burnt in a single good flame, the higher the proportionate light obtained, and it is therefore much more economical to light any given room with one large burner than with two or three smaller ones. The light of any burner can be increased by turning the jet until it slopes slightly downwards instead of upright, making a horizontal saucer-shaped flame; but this also has the practical objection that if turned low it is very liable to smoke.—THOS. FLETCHER.

[52639.]—**Netting.**—The instruments for netting consist of a needle (B) and a mesh, A, see Fig. 1. From 8in. to 10in. is a good length for the needle, while the mesh stick must vary according to size of net. A mesh stick will make a mesh twice its own size. Thus, a stick ½in. square will make a 1in. mesh. To fill the needle, pass the string round the tine, or inside point, round the heel of the needle, then up round the tine again, until the needle is full. Now fasten the end of the string to a hook and tie a loop in it, Fig. 2. Then lay the mesh stick underneath the string, and pass the needle up through the loop, Fig. 3. Then pull it tight, so that the end of the loop rests against the mesh stick, Fig. 4. Now comes the important part—the formation of the knot. Hold the mesh stick in your left hand with the thumb on the string, and with the needle in the right hand; now with a quick jerk throw the bight or loop of the string over the stick and left wrist, as shown in Fig. 5.





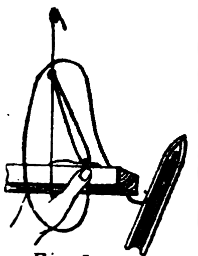


Fig. 5

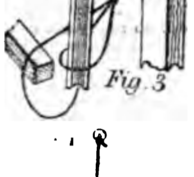

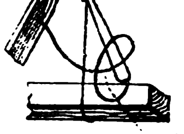

Fig. 6.

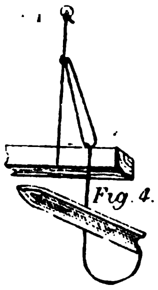

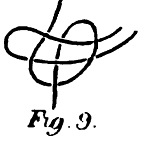

Fig. 9.

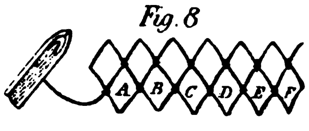
Fig. 7.

Fig. 8



Then push the point of the needle up between the first loop made and the string to the left of it, pull the needle through, and bring the knot into shape (Fig. 6), then tighten by pulling the needle in the direction of the dotted lines, and the knot is tied. This simple knot is the foundation of all net-making, and once succeed in that and you will very soon be able to manufacture almost anything. Now slip out the mesh stick and take the same stick through the loop you have just made, and so continue on, passing the needle every time through the last loop made, until you have made enough. By the time you have made as many as you think requisite, your work ought to look something like Fig. 7. Now unfasten the end from the nail and untie the first loop made. Now pass a piece of cord through the upper row of meshes, tie the ends of the cord together, and hang it over the hook. Now go on with the work as before, only do not slip the loop off the stick as at first. Knot through F (Fig. 8), then through D, then C, and so on, until you have travelled along the whole width. Then turn the work over and travel back again in the same manner. Presuming the string breaks, or you wish to join another ball, the way to do it is with a "becket-hitch," commonly called a "wêaver's knot." Form a bight, pass one part up through it, then over, under and back through its own loop, Fig. 9.—CHEMICUS.

[52643.]—**Silber Lamp.**—Defect is in the reservoir. Take burner out and empty all oil out and rinse with clean oil; replace old cotton with new, then light up.—W. JONES, Viaduct-street, E.

[52643.]—**Silber Lamp.**—What F. Search complains of is the great fault of the Silber lamp. The wick not forming a complete circle, the two edges of it tend to separate as it is wound up. When the separation exceeds ⅛in. or more, gas forms in the open space, and it is the explosions of this which put out the light. To cure it, see that the edges of the wick are in contact before lighting.—M. D.

[52649.]—**Varicose Veins.**—"Poor Sufferer" should get an elastic stocking, to be worn when out of bed; or, if he wishes, he can have it radically cured by a surgeon with but little pain or risk. The stocking is only palliative; the operation is curative.—M. D.

[52649.]—**Varicose Veins.**—My experience, which is for more than a quarter of century, is that a flannel bandage is far better than any other. I adopted it by the advice of an eminent surgeon (the late Dr. Cusack, of Dublin). Fine flannel torn the lengthway, 3in. wide, to allow for washing—mine are eight yards long, as I have to wear from toes to over the knee. I buy from three to five yards of flannel, tear it in strips, and put them together with a flat seam. In putting it on the edges should be well overlapped, and where a crease occurs from the varying shape of the leg, fold over the bandage so as to have it perfectly smooth.—M. B.

[52649.]—**Varicose Vein.**—Much more effectual than ordinary surgical bandage, and much cheaper than an elastic stocking, is Esmarch's bandage—a surgical elastic bandage. With this my one leg, in which there had been obstruction, has been reduced an inch and half in circumference, in three months, even when measured after the day's walking. "Poor Sufferer" should learn to put it on in a figure of eight, and will find it the greatest comfort and support. On no account fasten it with tape—the reason why not is obvious. Use a safety pin. Some doctors recommend Miller's (I think) bandage as a certain cure for varicose veins. It is a strong bandage of uncovered indiarubber; the cost is, I believe, a guinea. Esmarch's bandage, which is cheap, has been more benefit to me than the best elastic stockings that I have been able to get costing 30s., and worn out in a few months.—H.

[52653.]—**Electrical Currents.**—The matter can be best explained by attention to the following simile, which appeared some time since in a popular magazine, "Let the resistance be represented by a ditch, which varies in width at various points of its course. Now, you have a plank 10ft. long and 1ft. broad, and you take it to where the ditch is 10ft. wide. It is clear that at this spot the plank will just stretch across. Now go to a spot 20ft. wide, and saw down the centre of the board, so as to cut into two boards of ½ft. width. By joining the ends we get a plank 20ft. long and ½ft. wide. Now take your plank to a place where the ditch is 5ft. wide, then you will have to saw your board across and join sideways, obtaining a plank 5ft. long and 2ft. wide. Thus the broader the ditch, the narrower and longer the plank; and the narrower the ditch the wider and shorter the plank—the quantity of wood always being the same." The ditch is ohms and the plank watts; the length volts, and breadth of plank, ampères. Does not "Antares" see that it is not the current that is spoken of, but the energy? Cannot a current carrying 4 watts of energy be represented as 4 volts and 1 amp., or 8 volts and ½ amp., or again, 2 volts and 2 amp.? And with a fixed E.M.F. the current may vary in ampères (as in the case of adding cells in multiple arc). With respect to "Antares's" last two queries, I presume he refers to the pressure of the "magnitudes" at the same time. This can only mean W = E C, where W = energy in watts, E = potential in volts, and C = current in ampéres. The amount of energy cannot be measured directly on the galvanometer, but it can be on a watt meter. If the querist wishes to have a thorough comprehension of the subject, together with explanation of the chief instruments employed, he cannot do better than obtain Mr. Shoolbred's lecture on measurement of electricity in the *Society of Arts Journal* for April 6th, 1883, or in the *Electrical Review* for April 14th and 21st—preferably in the former, as they are illustrated therein.—COSMOS.

[52653.]—**Electrical Currents.**—My inquiry, 52653, has elicited three such important replies, that perhaps you will allow me to supplement it by the following extracts from the Parliamentary Report on the Electric Lighting Bill Committee of 1882, proving that, by the distinguished witnesses named, current is regarded as possessing two qualifications:—"2197. Mr. Spottiswoode: Currents having sufficient strength or quantity, and sufficient E.M.F. or tension. These quantities are perfectly measurable, and suffice to define the current or supply." "2475. Dr. Siemens: With a potential of 150 volts no danger would arise in the case of a man standing near a naked conductor." "2565. Dr. Hopkinson: Electric energy can be distributed, being taken in the form of great pressure and little quantity, or a little pressure and great quantity—just as water can." "2841. Electricity can be defined to the consumer as gas of so many ampères and so many volts." There are others to the same effect; and it would seem that the volt, or E.M.F., is no longer to be confined to the battery or dynamo as a measure of the generating force; but is to be considered as also belonging to the current which is produced. The passage in Mr. Sprague's book is that on page 205, which "Sigma" mentions. I am delighted to hear that a new edition of this work is so nearly ready; for the work as it stands has often cleared up for me difficulties raised by reading other textbooks. And as currents are now admitted to vary in "density," of which the galvanometer takes no cognisance, it is to be hoped some other instrument may be described *which will*. The water analogies which "Electricus" says are "quite wrong" were quoted from memory; but I think the illustration was, that just as a wide and voluminous mass of water with a fall of, say, 3ft., may yield the same horse-power as a far less quantity of water falling from 30ft., so two electrical currents possessing different qualities of "tension" may have the same effective power in producing light or motion. I do not understand this, I confess, especially as it is stated that one of these two currents (having "high tension" may kill a man who places himself in the circuit; whereas the other (having "low tension") may be handled with impunity. As to measurement, the following from the same Blue Book is interesting: but the apparatus measures "electricity" in the lump, without distinguishing between the component parts of the current:—"3102. Mr. Johnson (Edison's agent) describes a meter as measuring accurately the $\frac{1}{80}$th part of the current which the consumer uses. This is done by electric deposit, two metal plates in a solution being weighed at intervals, and the mean of the loss of one and the gain of the other is known to represent the $\frac{1}{80}$th of the total electricity that has passed into the house." Perhaps it may be taken that the terminology of the science is not quite settled yet; and as the volt has been found susceptible of two applications, it may be hoped that a similar economy can be practised with other units also, and that the philosophers will not insist in requiring the whole array of volt, ohm, ampère, coulomb, and farad, besides erg, dyne, watt, and joule, to express the practical phenomena of electricity.—ANTARES.

[52656.]—**Electric Communication.**—I should recommend Mr. Brown to use No. 22 or 24 cotton-covered copper wire for connections if indoors, and tape-covered wire tarred for outside work.—JOHN HALE, Univ. Coll., London.

[52658.]—**Expansion Valve.**—The very name of the valve points out the advantages—viz., the expansion of steam; consequently, the saving of steam. You give no particulars whatever by which you can receive a reliable answer. But if your valves are worked by eccentric, place the expansion eccentric with its full throw opposite the crank; now move the piston forwards, the distance you wish it to have travelled when steam is shut off. See if the expansion valve is closed; if not, close it by the division-thread, and your valves are set.—ENGINEER, Dewsbury.

[52659.]—**Soft Spelter.**—For iron, equal weights of copper and zinc; for silver, melt two parts of silver, then add one part of clean brass wire. If required harder, add more silver; if softer, $\frac{1}{30}$th part arsenic.—P. WARD.

[52659.]—**Soft Spelter.**—A good way of brazing light ironwork without heat at all is to take 2oz. of brass filings and 1oz. of steel filings, and put them into ¼oz. of fluoric acid in an earthenware jar.

[illegible] the work with them and press [illegible] can make a white solder for [illegible] silver with [illegible] of tin.—JOHN HALE, [illegible]

[illegible] — **Electric Gas Lighter.**—The proper [illegible] for charging this battery are: Sal-[illegible] grammes, water 1 pint. I presume [illegible] to be a chloride of silver cell; if so, the [illegible] in a film of oxichloride of zinc being [illegible] the Zn, or perhaps all the silver chloride [illegible] reduced to metallic silver. In the former case [illegible] per cent. hydrochloric acid added to solution will effect a cure; if the latter, the remedy is [illegible].—P. WARD.

[illegible] — **Royal National Tricycle.**—If "[illegible] S." has fitted his key properly, and it should be made of steel, I cannot see why it should work loose. I take it for granted that it is a taper key, and the same width as the flat; but it would have been better to have been sunk in the axle slightly, as there is a great strain on any key. He does not require to keep taking his fast wheel off, as, if he does so very often, he will not keep all tight very long, and the axle does not require cleaning where it does not revolve; it is different with the loose wheel. Just ask some friend who is a fitter to have a look at it, and he will put it right very soon, unless it be botched to begin with. Do not be annoyed at plain speaking.—SECUNDUS HAUD ULLI.

[illegible]—**Bristol and Exeter Single Express.**—If "H. N." would be a little more explicit perhaps we could inform him. What engine does he refer to? What number? The B. and E. Co. has been defunct these six or seven years; but several of their broad-gauge single engines, now G. W. property, are still running.—W. B. P.

[52665.] **Water-Blower.**—If "Young Engineer" will purchase "A Handbook of Applied Mechanics," by Dr. Evers, published by Collins and Co., London and Glasgow, price 1s. 6d., he will find, besides the information desired (on page 181), a great deal of other information.—C. C. M.

[illegible] **L. B. and S. C. R. Engines.**—There are about [illegible] engines of the 194-200 class, same as 371 Norwood, &c., unless some more have been scrapped lately. Grosvenor is the only 6ft. 9in.; she is now numbered 326, and reckoned first of the [illegible] class, being practically of same dimensions. When first built in 1871 she was No. 151.—W. B. P.

[illegible] **L.C. and D. Engines.** There are six of the Constantine class viz. 127 Adrian, 128 Trajan, 129 Vespasian, 130 Tarquin, 131 Pertinax, 132 Constantine. They are built by John Fowler, Leeds, [illegible]. The Sharp Stewart goods are numbered 113 [illegible] inclusive, the names being Aris, Calypso, Diomede, Fortuna, Gordius, Pyramus [illegible] Aurora.

[illegible] **Continuous Steady Temperature.** [illegible] temperature for 72 hours continuously is a [illegible] matter to obtain. If the experiment is worth the cost, perhaps the best way is to use gas with a good pressure governor in the supply-pipe [illegible], and a second governor [illegible] to correct the errors of the first. With these a perfectly steady flame can be obtained under [illegible] pressures of gas, and it is only necessary to protect the flame and the substance to be heated from draughts. Good governors are [illegible] moderately good approximation to a steady [illegible] may be obtained by a common [illegible] lamp with a large flat reservoir, using [illegible] ordinary petroleum. This, if the flame is turned low enough not to smoke, will [illegible] half hour, give a flame which is practically steady for 12 to 14 hours without attention [illegible] lamp can be prepared so that a [illegible] every 12 hours. If a reservoir [illegible] the lamp, say, 7in. or 8in. [illegible] that there is little variation in the [illegible], and a first rate quality of [illegible] lamp will burn with perfect [illegible] 20 hours or longer, and the oil [illegible] without requiring a second [illegible] of the ends of the [illegible] with a penknife blade. [illegible] and be raised during the [illegible] half an hour after cleaning or [illegible] temperature must be watched, [illegible] by allowing the [illegible] substance to be heated and [illegible] petroleum lamp [illegible], of [illegible] high temperatures, [illegible] supply governed by [illegible] absolutely necessary; [illegible] lamp will do all which "Heat" [illegible] THOS. FLETCHER, [illegible]

[illegible] I cannot at [illegible] for replying to [illegible] some Derbyshire [illegible] for me. WM. [illegible]

[illegible] "Corporal" would find that washing them in warm soapsuds and water will clean them better than anything else; a little soda would also help. When well washed, rinse them out and hang up to dry. This is the way I treat mine, which I find are as good after a wash as new ones.—A. E. WEBBER.

[52677.]—**Casting Lead.**—If the lead is made hot enough, it will run easily.—NUN. DOR.

[52677.]—**Casting Lead.**—If "X. L. C. R." melts 1 part of antimony with 7 of lead, he will have a fine, soft metal, as used for large and soft type.—JOHN HALE, Univ. Coll., London.

[52677.]—**Casting Lead.**—"X. L. C. R." is not likely to find any material which can be mixed with lead to make it run easier. No metal is easier to run, to make good castings, and any addition is likely to make it worse rather than better.—T. FLETCHER, Warrington.

[52678.]—**Printing Inks.**—Boil linseed oil, stir well; set a crust of bread floating on the top, and apply a light (must be done in an extra large pot and in a safe place, not in the kitchen); let it burn for half an hour, but remove from fire; then add about 3lb. of rosin to every gallon of oil; and some add as much soap or more. Put on the fire and stir well. That's the varnish. Grind up the desired pigment in it with a muller, and there's the ink; but most people buy it ready ground and thin down with varnish.—NUN. DOR.

[52678.—**Printing Ink.**—Take some old linseed oil, and boil it in an iron pot with a rather tight-fitting cover. When it becomes inflammable, light it, and burn for ten minutes, then extinguish by putting on lid. Mix with it some black rosin. Then add some yellow rosin soap (if not added, the ink would accumulate on the face of the type), the proper proportion being found when the ink works clean. When cool, mix this oil with vegetable lampblack, forming a thick paste when finished by grinding very fine with a muller. Don't forget to boil the oil out of doors.—JOHN HALE, Univ. Coll., London.

[52678.]—**Printing Inks.**—The general mode of preparing these inks is by boiling linseed oil, setting fire to it, and allowing it to burn for about twenty minutes or half an hour. This produces a sticky varnish, which is very finely ground with the colouring matter required. Different manufacturers make various additions of their own, but of course, these are secrets. Here is an ink made from rosin oil: melt 1lb. of rosin oil and 13oz. of rosin, with 1¼oz. of soft soap. When it is cold, add the desired colouring matter. For other recipes, see my answers to queries 52182 and 52208, on p. 308, of No. 976.—W. HENLEY RICHMOND.

[52678.]—**Printing Inks.**—Black: Six quarts linseed oil, boiled till the vapours that rise will ignite, then it is taken off, and stirred with an iron spatula, and kept burning. When the oil has reached the consistence that it will draw out strings about half an inch long it is ready. The flame is then extinguished by putting a cover on it, and then 6lb. of amber or black resin is gradually stirred in, then 1¾lb. of dry turpentine soap, cautiously added. The pot is then replaced on the fire, and stirred till it boils: this completes the varnish. In an earthenware tub is placed 5oz. of Prussian blue, and 4lb. of mineral lampblack, and 3½lb. of good lampblack: to these the varnish, while warm, is added, and thoroughly mixed. The whole is passed through a levigating mill, which reduces it to impalpable fineness.—WALTER H. INCE.

[52683.]—**Bartolozzi.**—This exhibition was held in Saville-row, but I do not remember the number. It was almost the last house on the left-hand side.—JOHN HALE, Univ., Coll., London.

[52685.]—**Octave Coupler.**—I can only advise Mr. W. Ireland to seek an opportunity to examine an American organ in which an octave coupler is employed. This will give him a better idea than any amount of words can convey to him. I am not quite certain that an octave coupler can be applied to the harmonium successfully, and if the querist has never done anything of the kind before, I imagine that he will find it a somewhat difficult undertaking. You will find a short description of an octave coupler to the American organ in some of the back volumes; but you will not find it so convenient to apply the coupler to any harmonium unless the necessary arrangements for its application have been made previous to the arrangements of the other portions of its interior construction. If you wish to apply the coupler to any harmonium already completed, I should strongly advise you to discard the idea.—G. FRYER.

[52685.]—**Octave Coupler.**—If Mr. W. Ireland will tell me that the following pages cannot be referred to because the Nos. containing them are out of print, I will see what I can do to help him to make an octave coupler:—p. 435, Vol. XV.; pp. 145, 275, Vol. XXII.; or p. 436, Vol. XXIII. All that is necessary in making an octave coupler is 49 levers placed diagonally, and pinned at the centre on a rail which can be made to rise and fall. One end of these levers is in proximity to a screw put into the under side of a key; the other is attached by a flexible link to the pallet an octave above or below. Another simple arrangement (perhaps the best) is to bend some pieces of wire at the ends in the reverse direction, so that when one bent end is depressed, the wire revolving (in collars) opens the pallet, because that is attached to the other bent end or arm. In the first described coupler the levers may be either wood or metal. I prefer metal.—ORGANON.

[52689.]—**Gold Washing.**—I think "Washer" is mistaken in the use of the word "magnetism." Electricity is used for the purpose he names by a company called the Electro Amalgamator Company. The ore, or washings, as the case may be, are made into a paste and mixed with water, which is made to flow bodily over a long trough of mercury. The mercury is connected to the negative pole of a dynamo, or suitable battery, and the stream of water and ore to the P. The result is that the mercury readily dissolves all metallic particles contained in the flowing paste.—P. WARD.

[52694.]—**Furniture Cream.**—(1) Put 4oz. of soap and 1lb. of beeswax cut into thin pieces in one gallon of soft water. Having boiled the mixture well, add 2oz. of pearlash. When using, dilute it with water, and lay on with a paint brush, and lastly polish off with a hard brush or cloth. (2) Mix and heat together 6oz. of water, 2oz. of pearlash, and 3oz. of wax. Then add 5oz. of spirit of turpentine, and 4oz. of boiled oil.—W. HENLEY RICHMOND.

[52694.]—**White Furniture Cream.**—Here are three good recipes for it. 1. Yellow wax 4oz., yellow soap 2oz., water 50oz.; boil, with constant stirring, and add boiled oil 5oz., and oil of turpentine 5oz. 2. Soft water 1 gal., soap 4oz., shavings of white wax 1lb.: boil, and add pearlash 2oz. Lay this on with a paint brush (diluted with water), and then polish off with a hard brush or cloth. 3. Take of wax 3oz.; pearlash 2oz., and water 6oz. Heat together, and add boiled oil 4oz., and spirits of turpentine 5oz.—JOHN HALE, Univ. Coll., London.

[52697.]—**Damp-proof Glue.**—Good glue dissolved in spirits of wine will make a water-proof glue, as also will isinglass, with methylated spirit; a little heat will serve to melt in a gluepot.—A. E. WEBBER.

[52697.]—**Damp-proof Glue.**—I should think the glue referred to by Alex. Finlayson is the American fish glue, certainly wonderful stuff, and if he will advertise his address will send him the method of preparing it—costs nothing and is invaluable for persons using glue for any purpose.—ARCHITECTUS.

[52697.]—**Damp-Proof Glue.**—The glue which the "American" showed Mr. Finlayson was probably a mixture of 2oz. of unslaked lime-powder mixed with 4oz. of linseed oil, and boiled to a good stiff consistence. He can make waterproof glue by simply boiling 1lb. common glue in 2 pints of skimmed milk.—P. WARD.

[52698.]—**Gas for Boiler.**—Such a boiler as "Amateur Engineer" describes is extremely difficult to heat by gas to get any amount of work out of it. A gas burner is extremely liable to smother in a long horizontal tube, and no really satisfactory burner can be devised to work under such conditions unless it is supplied with a blast of air under pressure. It might be possible to devise a burner which would work under the conditions named, utilising the draught of the chimney; but such a burner would both need to be constructed specially, and would require some experience and knowledge to get it to work at all. It would be a very much simpler matter to use one or more burners underneath the outer shell. In such a boiler, externally fired, it would probably take 20 to 25 cubic feet of gas to evaporate 1gal. of water. The boiler is constructed to burn solid fuel, and is therefore totally unsuited for burning gas economically.—THOS. FLETCHER, Warrington.

[52700.]—**German Yeast.**—I should advise you to use Avant yeast, 2½lb. to 280lb. of flour. You need not be kept waiting at any time; sponging is not essential, ferment only. It would be ready for doughing from 30 to 90 minutes. As regards temperature, use your own discretion, according to weather. If you do not prefer this, and have had good results previous, all you require is extra plant.—CYPHER.

[52702.]—**Water Power.**—A pipe 9in. diam., head 1ft., length 400ft., will deliver roughly about 350 gallons per minute.—WATERMAN.

[52704].—**Piano.**—A modern action applied to an old cabinet piano would not be likely to produce very good results. As the present hammers show signs of hardening, rather than of cutting, I presume they are covered with leather; if so, it would greatly improve the tone, and take away the disagreeable metallic ring if a thin covering of felt were used instead. But, with a softer tone, many

other defects would become prominent, and he would probably find it necessary to cover the dampers, clothe the hammer centres, and renew the leather and parchment hinges throughout. The cost of all this would, if properly done, be certainly more than the piano would be worth when finished, so that in such a case it is very hard to advise. Should "E.," however, have plenty of time on his hands, and like to undertake the repair himself, I will do my best to help him.—W. H. DAVIES.

[52706.] — **Bottle Batteries.** — "Scrutator" will find that the most suitable battery for his 5-candle power lamp is a series of 10 or 12 bottle bichromate batteries, plates about 4in. by 6in. or 3in. by 8in., according as he can purchase them. There is a battery, which was a patent one, manufactured by Apps in the Strand, in which both carbon and zinc were raised at the same time. I have had one of these in use ten years, and, apart from occasionally having to renew the zinc, it is as good as new.—P. WARD.

[52707.]—**L. and S. W. R. Brakes.**—I am afraid H. W. Hudson must have been misinformed. Most engines on this line are fitted with steam brakes, but not automatic ones. The action of these steam brakes is entirely independent of the vacuum brakes on the trains, it being quite possible to use one without the other.—MACHINA.

[52708.]—**Stop for Photo Lens.**—I am not aware that there is any definite rule, the best position depending a good deal upon the construction of the lens. An extemporised stop fixed a little closer to the lens will remedy the defect complained of.—W. ROBINSON, JUN.

[52712.]—**Coupling Railway Waggons.**—If "Historian" can refer to the back vols., he will find several of these couplings, and a good deal about them; but, if he wants to know all, he must get a list of the specifications at the Patent Office (some hundreds). I don't think there is much chance of an automatic coupling being adopted under present arrangements, for there are obviously great difficulties in designing one that meets all the requirements, and when it is designed the railway managers would tell us they prefer the simple stick with a hook by which to lift the link and put it over the hook. Even where that is provided I don't think many of the men use it.—NUN. DOR.

[52715.]—**Steam Launch.**—An ordinary rowing boat would do if slightly altered. I do not think you would be able to go so fast as you mention; you might get 10 miles an hour, which would be a good speed for so small a boat. Further information I will give if you will advertise your address.—TIT BITS.

[52717.]—**Wollaston's Battery.**—I must inform our reader that his battery (which he thought was out of order) has nothing at all the matter with it; but simply the action which takes place in these form of batteries. Very great improvements have been made in the construction of the batteries, but still there is one decided inconvenience—viz., that after a short time they lose their power, which occasions them to act with a variable force during the same course of experiments. The zinc plates soon become covered with sulphate of zinc, and the copper plate with hydrogen, and even oxide of zinc. These deposits not only reduce the power of the battery very much when in use, but also require the plates to be cleaned, or renewed if worn away much, before they can be put into action again. In order to avoid these inconveniences, Bunsen, Grove, and Daniell have invented their constant batteries, where the porous partition, by which the principle of these batteries are constructed, without interrupting the conduction of the voltaic fluid, prevents the accumulation of depositions on the plates, or very little; for when a Grove's or other similar kind is put in action, the decomposition of the diluted acid does not attach itself to the platinum plate, but goes to change the nitric acid into nitrous acid, and the oxide of zinc remains in the diluted acid cells without penetrating to the platinum plate, which consequently remains perfectly clean; this circumstance essentially contributes to keep up the power and constancy of the battery, which renders it so valuable as a voltaic combination.—ELECTRICIAN.

[52718.]—**Dog Poisoning.**—Prussic acid or cyanide of potassium. Too virulent to be painful, and a very small dose sufficient—a few drops of the acid, a few grains of the cyanide. The assistant of any medical man would, I should think, settle the matter for a small fee.—NUN. DOR.

[52718.]—**Dog Poisoning.**—Mr. "C. H." would find that laudanum would have the desired effect—rather slow, but not much pain; a sort of sleepy stupor would come over the dog, and then he would die. For my own part, if I wanted to poison a dog I should use Prussic acid, about five drops on bread or sugar, or in milk, and pour it down, first chaining and securing him. Strychnine is another powerful drug; but should not prefer myself to use it, as it would require a larger dose.—A. E. WEBBER.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

Since our last W. Robinson, jr., has replied to 52354, 52365, 52371; A. Gray, 52362; W. J. Grey, 52377-8.

QUERIES.

[52725.] — **Long-Focus Telescope.** — My best thanks are due to "A Fellow of the Royal Astronomical Society" for his kind answer to my query. His courtesy encourages me to trespass still further on his good nature by putting a question, the answer to which will, I hope, come directly home to the point about which I am puzzled. We take an achromatic of 2in. aperture, and 30in. focus, bearing on a planet 120. The focus of eyepiece required to produce this result is ¼in. Now to double my power I apply an e.p. of ⅛in., but the resulting definition is unsatisfactory. Replace now the o.g. by another 2in., but of 60in. focus; and with the same e.p. as at first you get the magnifying power which you raised (but with unsatisfactory results) by the ⅛in. e.p. on the 30in. objective. Double the focus of your o.g. again, and with the same ¼in. e.p. that at first raised 120, you get 480. This is doubtless an extreme case; still it looks as if with a similar lengthening of the focus of common telescopes a gain could be effected in magnifying power, and (there being no costly increase of aperture) without the usual additional expense. The one great objection I see is the rule of "100 to the inch," but this is evidently not without its exceptions. I beg to assure "F.R.A.S." that my query is not put out of mere curiosity, but under the impression that if there is a substratum of truth in the above a door might be opened for increase of magnification without additional expense, which to the amateur with small means would be no trifling boon.—ARTHUR MEE.

[52726.]—**Fishing Flies.**—Are the feathers of the golden plover good for making flies? If so, from which part of the bird should they be taken, and at what time of the year might they be used? Also, what is the best sort of varnish for the heads of the flies?—SALVO JURE.

[52727.]—**Quantity of Water used per Hour, and Rule Wanted.**—Would any of "ours" give a simple rule of calculating quantity of water drawn from ⅜in. tap per hour? Pressure of water 40lb. sq. in. Also at 60lb. and 50lb.?—A. E. WEBBER.

[52728.]—**Deposit in Water Cistern.**—Living in a three-story house, the galvanised iron cistern on third floor is supplied from the town main by ball-tap. The hot-water galvanised iron cylinder is on second floor, and cast-iron boiler behind kitchen grate on ground floor. Now I would be much obliged if any of your correspondents can tell me the cause and remedy why the sides of the cistern, within a week after cleaning out, are covered with a soft red spotted rust, which, upon the slightest movement of the water—say running half off for bath,—becomes detached, and causes the water to be very muddy and unpalatable.—ENGINEER.

[52729.]—**Bronzing Mounts.**—Will one of our readers kindly inform me how the bronzing is done on card used for picture-frame mounts, as I cannot get the card already bronzed?—A. E. R.

[52730.]—**Legal.**—I have one of Clayton and Shuttleworth's portable engines, which I use for circular sawing. The piece of land on which it is erected is on a lease for about 76 years. It is about 23 yards from the street, and not near any houses, and the stack is a high one. The ground landlord says he will make me shift it—the landlord of adjoining property having taken offence, he saying it is an annoyance. Can you tell me whether a sawmill is considered a nuisance in law? The lease that I have forbids turning the property into a nuisance. I suppose the same is in every lease. Do you consider that he can compel me to shift it?—PORTABLE.

[52731.]—**Axle of Electrical Plate Machine.**—Will some practical reader of "ours" kindly furnish me, and others who need the information, with the details necessary to mount a glass plate 2ft. diameter, ¼in. thick, on a suitable axle? I have tried wood, but should like something better. The plate has a ¾in. hole in centre. Would a ¾in. rod of glass or ebonite be strong enough to stand the weight and strain? How are the bearings made, and of what material, and how are the caps to keep plate in centre cemented on? Why would not metal do?—the glass could not conduct the electricity to the axle. What length spark ought a machine of this size to give, constructed on Winter's principle, with 8in. ball for prime conductor, but without ring?—W. H. H.

[52732.]—**Permanganate Stain in Carpet.**—I should be glad if any one could inform me how to remove a large stain on Brussels carpet, caused by upsetting some of Condy's pure fluid. I have well washed with cold water; but the mark still remains—almost a black patch.—A CONSTANT READER.

[52733.]—**Finding Speed of Trains.**—I shall be pleased if some reader can tell me how many times Mr. Webb's new compound engines beat or "puff" to each turn of the driving-wheels, and whether the steam blast is as sharp or loud as in the ordinary single engines. I shall also be pleased to learn whether it is possible to find the speed at which at engine (non-compound) is travelling by noting the number of puffs the engine makes in a second? For instance: The steam-blast strikes the chimney-cap of an 8ft. driving-wheel engine between 11 and 12 times per second. At what speed does the engine travel? Can "Historian" oblige?—C. R. K.

[52734.]—**Paper Tubes.**—Will some kind reader give particulars of tools or machinery required for making paper tubes from ½ to 2in. diam., and from 6 to 18in. in length?—TUBES.

[52735.]—**Coloured Pencils.**—Will any reader inform me what is the colouring matter of the red and blue drawing pencils sold in the shops, and the method of preparing it?—ROUGE ET BLEU.

[52736.]—**Gelatine.**—Can any of your readers inform me if it is possible to make gelatine from ham rinds, or if the same is used in the manufacture thereof?—GELATINE.

[52737.]—**Steam Boiler.**—Will any reader who is a practical man tell me which is the safest and most durable form of steam boiler—the egg-ended shape, or the square end?—STEAM.

[52738.]—**To Fasten Fan Blades and Arms on Spindle.**—Would any reader give information for fixing six arms of fan on ½in diam. spindle? Arms of fan ¼in. diam.—SANDY SAM.

[52739.]—**Electric Bell.**—Will some electrical correspondent describe method of making electric bell to ring when a door is opened?—I want one that will only ring for a short time, and then stop—whether the door is left open or shut. Also good form of battery, with some substitute for usual earthenware porous cell.—CHEMICUS.

[52740.]—**Drying Damp Room.**—I should be glad if any one could tell me a means of drying a damp room, which has no fireplace in it. There is a good deal of gas burnt in it, which probably increases its natural dampness. It would be very inconvenient to place a stove in it, as the room is a small one, which is plenty warm enough without one. I have a lot of books in the room which I am afraid are being damaged by the damp. Is it possible to dry the part surrounding the bookshelves (which are not cased in), without bothering about the rest of the room?—C. J. N.

[52741.]—**Aneroid Barometer.**—I have a small pocket aneroid barometer which was accidentally let fall about six weeks ago. Since that time the index hand has remained at the same point. Is it possible for me to put it into working order again myself, or had I better send it to a professional?—C. J. N.

[52742.]—**Upright Tool.**—I have a watchmaker's English upright tool with the ordinary hand-rest. I wish to put a slide-rest on. Could any one tell me how to do it, showing a description of the same?—R.

[52743.]—**Lathe Saddle.**—Will "J. H." kindly inform me how to make a pattern for the above?—O.

[52744.]—**Marble.**—Will any of our kind readers tell me how to get bichloride of mercury stains out of white marble, and also iron stains?—E. BEAUMONT.

[52745.]—**Furnace.**—Will any reader instruct me how to make a small hollow fire or furnace, say to weld about 2in. square iron for light edge tool? I have a pair of 38in. bellows going by water power. Would that give sufficient blast? I have tried one, and that would not answer my purpose. The iron seems to melt off and wasting, and when I took it under my hammer the steel would fly in all directions, and would not weld. It was full of blisters, or some parts unwelded. Raw coal I used. Would a fan answer the purpose better than a bellows?—UNSUCCESSFUL.

[52746.]—**"Edco" Battery.**—Can any one add to the interesting account given of this battery by stating the amount of candle-power of incandescent lamp sustained by the two-cell battery for 90 hours?—DELTA.

[52747.]—**Electric Microscope.**—Can any reader kindly explain how this is worked? An exhibition of it was given, according to daily papers, on Saturday, Jan. 5, at the Crystal Palace, Sydenham.—DELTA.

[52748.]—**Railway Truck Springs.**—Will some reader oblige me with some information as to making and tempering truck springs? I have some to make.—A BLACKSMITH.

[52749.]—**Lime Green.**—Can any reader mention a good green colour which will stand when used with lime? Also a yellow, brighter than ochre, for the same purpose.—W. D. B., Dublin.

[52750.]—**The new "Edco" Battery.**—Can any reader say what is the object of having lead cells? Also are they united? Are the carbons insulated from the lead cells?—H. R.

[52751.]—**Recovering Silver.**—Would "Os," or any other, kindly say the best and cheapest way to recover the silver from bits of iron about 1in. long, ¼in. square, which have been electroplated? They are cropped from articles we have to mount, and are thrown away with the rubbish as no use. Would some one send a practical answer, and oblige a—SHEFFIELD WORKMAN.

[52752.]—**Clock to Strike by Electricity.**—I have a clock in distant part of house that strikes half-hours and hours. I should like to make a single-stroke electric bell strike same as clock. Can any of our able correspondents give me instructions, with sketch? Also, I have several clocks that I should like to regulate by same clock (marble, French eight-day). Will "Sigma" or Mr. Lancaster help me? At Town Hall, Shoreditch, I see hall clock is regulated by the Standard Time and Telephone Co. Can any one oblige with sketch of their system?—CLOCK.

[52753.]—**Copper Ores.**—Would some correspondent kindly furnish information to analyse copper ores by means of the galvanic battery, stating description and number of cells required?—X.

[527[illegible]]—**Japanese Scintellettes.**—Can any of your readers tell me how these are made—viz., what is the composition?—SHAKESPEAR, Dresden.

[527[illegible]]—**Lathe Bed.**—I am much obliged to "J.H." for the trouble he has taken about my bed pattern. I have been making inquiries at the foundries, and I find they object strongly to a cored gap. Can the gap be left out in the pattern without altering the core-boxes? How do the core-boxes open? The founders here are very fussy, and make much ado about little things that would be thought nothing of in England.—SHAKESPEARE, Dresden.

[52756.]—**Agriculture.**—Can any of your readers inform me where I can learn anything of the system or works of a Mr. George Reed (?), who made experiments under the Emperor Napoleon III., relative to the raising of cereals and the fertilising of barren sandy soils through chemical agencies—in both of which he was remarkably successful?—B. M.

[52757.]—**Silvering Solution.**—Please inform me if potassium cyanide argento (otherwise silver solution) will leave a deposit of silver on base metal, and if so, which will be the best way to apply it?—J. HALES.

[52758.]—**Speed Regulator.**—Can any one give particulars of the vibrator which regulates speed in Hughes' type-printing telegraph or any kindred form of vibrating regulator?—COSMOS.

[52759.]—**Deer's Head.**—Can any fellow-reader inform me how to remove the hair from an old deer's head without destroying the skin. Any information will be thankfully received by—INQUIRER.

[52760.]—**Safety Valves.**—Will any of "ours" inform me of the proper mode of adjusting safety valves? I want to adjust a valve to a boiler of 40lb. pressure. What proceeding must I take to have the valve properly adjusted?—PHONOGRAPHER.

[52761.]—**Phthisis.**—Having suffered for about four years with painful congestion of the right lung, accompanied by dyspepsia and much opaque expectoration, I should be very glad if some kind medical reader would prescribe me a remedy? I have tried cod liver oil, but cannot digest it. My age is 24, and able to work at my trade, which is not hard, being a sitting occupation.—M[illegible].

[52762.]—**Hens losing Feathers.**—I shall be obliged if any of your correspondents can tell me what ails my hens? A number of them have lost the feathers around the neck, and they have remained so all winter—some of them from last winter. Others are bare of feathers just in front of the neck. I have fed them twice a day on Indian meal "crowdy," as they call it here. They have any amount of field run, but rather a small wooden house to roost in. Any suggestions about their proper treatment and feeding will much oblige.—W. A. H[illegible].

[527[illegible]]—**Violin Measurements.**—Will any of our kind readers recommend to me a work (book) on the history and mystery of the violin, or give me the correct lengths of the strings from nut to bridge on a quarter, half, three-quarters, and full size instrument?—R. G. [illegible]

[illegible]—**M'Naughted Engines.**—Will any correspondent tell me what is meant by engines being M'Naughted? Also, what is a [illegible] valve, and what is the [illegible] and advantage, if any, over the ordinary slide valve?—W. [illegible]

[illegible]—**Prevention against Sparking in Electrical Contact Makers.**—Can Mr. Sprague, Mr. [illegible], "Sigma," "Electrician," or any of your readers versed in the subject, give me information to enable me to prevent sparking, and consequently fusion, of the platinum contacts in the make-and-break connection in an electrical apparatus I have. I may say the current I employ is generated from a battery of eight cells [illegible], coupled in simple series, and my electro-magnets [illegible] similar to those usually employed in electric bells. After some little time I find that the push contacts faced with platinum show signs of being badly [illegible] owing to the sparking at these points. What is the best means of [illegible] this?—[illegible]

[illegible]—**Magic Lanterns.**—I am desirous of purchasing [illegible] with refulgent lamps [illegible]. Will the [illegible] form of lantern [illegible] with this light? What is the [illegible] dissolving view slides register[illegible] It is here premised that [illegible] W.

[illegible]—**Lathe Bearings.**—Will some kind reader [illegible] of conical bearings for [illegible] explain how the wear is taken up?—A. [illegible]

[illegible]—**[illegible] Engines.**—I hear woeful [illegible] coupled engines (707 [illegible] Co., on the ground [illegible] differ in details from [illegible]

[illegible]—**Dynamo.**—[illegible] How many [illegible] supply if made twice the [illegible]? Will everything have to [illegible]?—H. H. W.

[illegible]—**[illegible] Clock.**—I have one of [illegible]. It will [illegible] and the rack [illegible] weight, [illegible] What is likely to be the cause? [illegible]

[illegible]—**Wimshurst's Influence Machine.**—[illegible] good enough to publish a [illegible] in reference to this [illegible] in combination with the [illegible] more than justifies all [illegible] as nearly as pos[illegible] as I got from the [illegible], but the spark [illegible] with the one, [illegible] with the other. How [illegible] (24), or therefore the distances between the sectors, or between the sectors and the bulb, are too short for proper insulation? Will some of your readers please enlighten me?—STUDENT.

[52772.]—**Tinning Bright Steel Goods.**—Will some kind reader put me right in the following? Having a quantity of bright steel goods to tin, I have tried the following solution: Dissolve 17½oz. of ammoniacal alum in 22lb. boiling water, and when dissolved add 1oz. protochloride of tin. The articles having first been coppered, are immersed in boiling solution. The result: a good deposit of tin, but very dull, except in one instance only they came out bright; but I have not been able to obtain the like result since. It is absolutely necessary the articles should be bright. Information as to the means by which I can effect this will greatly oblige.—I. P. R.

[52773.]—**Waterwheel.**—Will any reader tell me whether I could use a waterwheel under the following circumstances, and work a double-action lift-pump 5in. barrel, about 16in. stroke, with a small engine? I raise the water, say, 5ft. above the level of the ground. What I want to know is—Can the water be utilised in such a way as to assist the engine in pumping itself out of the pit? I can get a greater fall if necessary.—NARVA.

[52774.]—**Strabismus.**—To "S. M. P."—Many thanks for last reply. Would you kindly say how is electricity applied to the muscle of the eye in such case? Querist does not intend to apply it himself; but it would be an advantage to have an intelligent idea of the matter before proceeding further. Spectacles tried with little benefit.—EGO.

[52775.]—**Dynamo.**—To MR. S. R. BOTTONE.—I am making a dynamo half as large again as your instructions. Will you please give size and quantity of wire for use for lighting incandescent lamps, and what might I expect from it if driven by lathe?—J. R. C.

[52776.]—**Dynamo.**—Will Mr Bottone or some of my fellow-readers kindly oblige with the working drawings and full instructions for making a dynamo capable of generating current for three or four hours daily equal to 10-c.p. Swan incandescent lamps? How many horse-power will it take to work it at ordinary speed? I propose working it by a turbine, as I have the water at hand.—JOHN HALE, Univ. Coll., London.

[52777.]—**Water Turbine for Dynamo.**—Will some of my fellow-readers kindly oblige by giving working drawing for making a turbine capable of turning a 500 c.p. dynamo at ordinary speed? Kindly also state how much fall and diameter of leaden pipe it would require to drive it?—JOHN HALE, Univ. Coll., London.

[52778.]—**Dissolving Views—Registration of Effect Slides.**—Can any reader give me a good plan for the registration of effect slides? I have a bi-unial lantern, but find it difficult to get effect exact in its place. Take, for instance, view of church, effect of windows illuminated. Unless the window of view and window of effect exactly coincide, the picture is spoiled. I have tried several plans of my own, but not with the success I should wish. Any-one who has seen Mr. Malden's exhibition knows with what precision his effects are worked. Perhaps one of "ours" can give me his plan; or for any other I shall be thankful. I may add I use all sizes and thicknesses of slides, from a comic movable to a thick chromatrope.—FRED.

[52779.]—**Burning Clay.**—I have two or three fields of very stiff clay, and I want to give them a dressing of fifty or sixty yards of burnt clay to the acre. Now, I should feel obliged if any of your readers could give me a hint as to the best way to burn it, my fuel being furze bushes, faggots, and roots. A year or two back I got a couple of hands accustomed to burn ballast for the railways; but, notwithstanding my endeavours, I could not prevent them overburning it, rendering the product unfit for its purpose—that is, the amelioration of the soil. What is wanted is not a hard red lump, but the clay so burnt that it crumbles to dust between the finger and thumb, and when powdered and wetted does not again become plastic. I have heard that in the northern parts of Essex and borders of Cambridgeshire there are men who make a trade of burning clay for manurial purposes.—KHODA BUX.

[52780.]—**Bath Heater.**—Will some of your readers kindly inform me the best kind of bath heater? I have tried a variety, including Fletcher's copper tank with gauze burner, and also one of Sugg's patent "Therma's" with 20 gas jets; but even with the latter am unable to get the temperature up to 98° for a warm bath of 40 gallons in less time than 1½ hour.—J. H. HUMPHRISS.

[52781.]—**Battery for Lamp.**—In looking over some back numbers I came across, in Vol. XXXVII. No. 946, a description of a granule carbon battery by "E. F. F.," which I resolved to try, using jars of the following dimensions: Outer jar, 6in. by 4in.; porous jars, 6in. by 2in.; zinc, 6in. by 1½in.; carbon, 6in. by 1in. square. I constructed ten of these, and obtained a light equal to about 1½ candle with a 5-candle lamp, and, after working 6 hours, diminished to a dull red heat. Next evening I took out the zincs and gave them a thorough cleaning, after which I again obtained a light as before, but this time only 2 hours. Where is the fault? I am about to construct some larger cells. Am I liable to have the same trouble with larger ones? I use sal-ammoniac and hydrochloric acid for porous cell. 2nd. Thanks to P. Ward for his answer to former query. I had discovered my error before his answer reached me.—ROBERT S. HARGREAVES.

[52782.]—**Dynamo.**—Would Mr. Bottone, or any other electrical friend, kindly suggest a remedy for the better working of my dynamo? It has double-field magnets and Siemens armature. I excite the field-magnets with a three-cell bichromate battery, and get a lot of sparking at the brushes; but it will not come away from there. It will not red a five-candle lamp, though I have 7lb. 16 wire on each (4) pole of magnet, and 4lb. 20 on armature. I do not seem to get sufficient magnetism in the field-magnets.—WAG.

[52783.]—**Phenylendiamine.**—To MR. WM. JOHN GREY. Will you kindly inform me how to separate this base from tin, iron, or zinc chlorides?—DIPHENYL.

[52784.]—**Pedal Reeds to Harmonium.**—To MR. FRYER.—I have constructed pedals and bellows to attach to my four-row reed harmonium, as suggested by you some months ago. Will you kindly instruct me how to make the pan? There will be sufficient wind for two sets of reeds—viz., 16ft. and 8ft., which I have by me—1½ octave each. What proportion in length and size should each tube be for its reed?—STATION-MASTER.

[52785.]—**Hughes' Battery.**—Can any one tell me what is the E.M.F. and internal resistance of Hughes' sulphate gravity battery as used for microphones? Would reducing the thickness of sawdust materially diminish the internal resistance? Are three or four of these cells suitable for working a small medical coil consisting of five layers of primary coil?—BATTERY.

[52786.]—**Tricycle Crank.**—I am about to have a tricycle built for me. Having a particularly long leg, would it not be advantageous for me to have a crank with a little greater than ordinary throw? The mechanical advantage of (say) another inch to the crank would be very great, while the tread to my long leg would be nothing more than comfortable. This has no reference to raising the saddle, which is quite another matter. I should state that all my riding will be at easy speed—no racing.—J. K. T.

[52787.]—**Boiler Query.**—Would any of your mechanical readers suggest a remedy for the following?—A steam boiler working at 60lb. pressure, manhole door joints made with hempen rope, and red and white lead; blows every three or four weeks, and has to be remade. It used to go for months before; have had it thoroughly examined by boiler makers, and still the same. I would be glad if some one would give me their advice upon the cause, and how to remedy it.—A. G.

[52788.]—**Papier Mache Ornaments.**—What is mixed with the pulp? Can I make it thin enough to run in like plaster of Paris? Should the moulds be of wood or metal? How long before the castings are dry enough to use?—SAMPSON.

[52789.]—**Watch Repairing.**—Geneva watch stops at times. It is in beat, and every part is clean and free of action, but when going the balance has a bad swing, causing teeth of escape to ride on edge of cylinder instead of sounding sharp and clear. It has the sound of click similar to feeble beat of a lever. If any reader will kindly inform me how to alter the depth I shall feel greatly obliged.—W. R.

[52790.]—**Rotary Hook for Sewing Machine.**—Will some practical hand give a few diagrams and details of the best form of hook, spool, and spool holder, showing how the two threads are to be related, so as to enable a mechanic to make and fit up a machine of this kind.—LOCK STITCH.

[52791.]—**Indiarubber Gas Tube.**—I am using some black rubber tubing to connect a gas stove with iron pipe. The tubing gives off so strong an odour that one can scarcely believe but that the gas escapes. The odour is not diminished when the gas is turned off. Can any reader tell me if I can coat the tubing with any substance so as to remedy the evil?—E. EDWARDS.

[52792.]—**Steam Launch.**—I am desirous of making, or, if the task be too formidable, of having made, as small a steam launch, for river use, as is possible, compatable with quite safely carrying three, or at most four, people (one of whom would attend to engine), the weight of engine and boiler, say 1cwt. coals, usual boat gear, and usual camping-out requisites, which latter would be very simple and limited in quantity as much as possible. In addition to the foregoing an extra carrying or supporting power (buoyancy) would have to be allowed for, to provide for light contingencies and a very liberal margin of safety. There ought to be no danger of the boat turning over when the occupants move about in it, provided they are reasonably careful when doing so. There would be no cabin accommodation or other protection from the weather, except such as would be afforded by a waterproof canvas covering rigged up on light movable iron rods. The boat is intended to be used purely for pleasure purposes, short excursions, camping out, &c., and as it may be just the kind of boat that other amateurs, living, like myself, near a river, would like to possess, and whose requirements in this way are not ambitious, and possibly restricted by the pocket, I trust this query may be of general interest, and that fellow-readers will give me the benefit of their knowledge and experience. Would a boat 12ft. long from stem to sternpost (which latter is, I think, the name of the timber in which stern bush is fixed) be long enough, with say a beam of 4ft., and of such depth as would be necessary (there being no restriction as to draught), including a good freeboard? The total length of boat, including the counter or projecting part over screw and rudder, would possibly amount to 15ft. or so. May I solicit opinions on this point? Also, what should be dimensions of smallest cylinder capable of driving the requisite sized and loaded boat, eight or ten miles an hour, at a pressure of (say) 30lb., or at such pressure as would be recommended? Are there any books published on steam launch building for amateurs? and would it be preferable for me to have the hull built by a professional boatbuilder rather than attempt it myself? I am quite confident about making everything connected with the engine, and, with the help of a carpenter, feel sure I could build the hull if there is no special difficulty in it. What would be probable cost of engine and boat complete? I should be grateful for any hints on this subject.—H. H. H.

[52793.]—**Wall Fillings.**—I should feel greatly obliged if any reader would give me a rough sketch of some scheme for temporary fillings to two corresponding wall spaces in the east end of a church—something inexpensive that any one with an artistic turn of mind could do. Size of wall spaces about 12ft. by 8ft.—CHURCHWARDEN.

[52794.]—**Toning Prints.**—Will a photographic subscriber tell me how I can tone dry-plate prints so as to get out the red colour? I print them till they become a purple black.—VANGO.

[52795.]—**Extracting Alcohol from Oil.**—A few months back I read in "ours" of an experiment by which the alcohol in oils could be extracted, water being the chief power. Would some kind reader give again the details of this experiment, and also please say whether the oil thus freed is improved for lubricating or other purposes?—YOUNG OILMAN.

[52796.]—**Income-tax.**—I have property in New Zealand, on which I pay the usual taxes, including property tax. Am I legally bound to pay Income-tax on the portion of my income (£400) spent in this country?—COLONIST.

[52797.]—**Joining Electric Wires.**—In an article in the *Engineer* of the 12th inst., it is said that soldering electric wires is not necessary, and electricians do not know how to make a good contact without it. "Engineers will be happy to teach them," says this oracle; but it carefully omits to say how to do it. Therefore, I appeal to the readers of the ENGLISH MECHANIC, who are ever ready to help one another, to reply to the question. What is this method of joining wires which will answer as well as soldering?—S. M.

[52798.]—**Lalande's Voltaic Element.**—Can Mr. Sprague, or any of your electrical readers, give a brief description of the new Voltaic element of Lalande?—P. W. R. H.

CHESS.

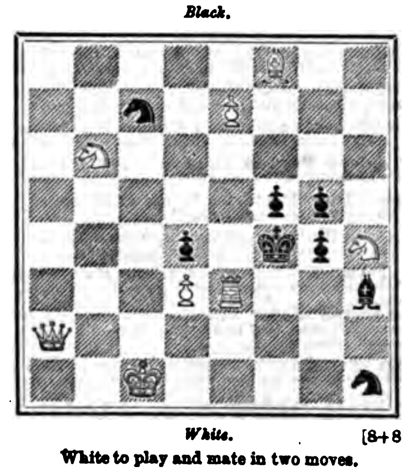
PROBLEM DCCCLXX.—By R. CRUESEMANN.

Black.



White. [8+8

White to play and mate in two moves.

SOLUTION TO 868.

White.	*Black.*
1. Kt from Q 8 to K B 4	1. Anything

(10 variations.)

NOTICES TO CORRESPONDENTS.

CORRECT Solutions to 867 by Dicky Sam, J. B. of Boxford (clever problem), E. Stanley Follwell; to 868 by Dicky Sam, J. B. of Boxford, A. Schmucke, E. S. Follwell (very neat), R. A. Bennett, J. G. E. (Sittingbourne), D. Millar, W. H. Evans, Rev. W. Anderson.

D. MILLAR.—Solutions must be sent within a fortnight after publication of problem.

A. C. HURLEY.—No mate if 1. $\frac{\quad}{\text{Q to B 4}}$

F. WEST.—The variations must be sent in full; otherwise marks not allowed. Where is the mate if 1. $\frac{\quad}{\text{P-Q 4}}$?

H. NEWMAN.—Look again at 867: you will see that Black can escape.

Boldo is the name of a plant indigenous to Chili. The leaves serve to make two preparations—viz., a tincture and a fluid extract. These fluids are prescribed in America for cases of adynamia and to strengthen the action of a feeble heart. An essential oil is contained in the leaves, which seems to exert a modifying influence on inflamed mucous membranes. Recent observations made by M. Verne seems to show that the quantity of urea discharged by the kidneys is increased without any change in the amount of urine excreted. Aromatic principles have been detected in the urine. The body heat and circulation are unaffected by these preparations.

THE greatest elevation that the Pike's Peak Railway will reach will be 14,146ft., making it by 2,000ft. the highest railway in the world. It is to be 27 miles long, with a maximum gradient of 300ft. in the mile, and maximum curves of 30 deg. It will be narrow gauge, and the trains will be composed of three carriages, each carrying forty passengers. The line is being laid out with a view to scenery, so as to command the finest possible views of the magnificent scenery of the Rocky Mountains, and open up attractive sites for hotels, sanataria, and camping grounds for summer tourists.

ANSWERS TO CORRESPONDENTS.

◆

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 16, and unacknowledged elsewhere:—

E. HOTHAM.—L. Von Malein.—J. K. Esdaile.—W. Erck.—R. McCowen and Sons.—C. E. Miles.—W. P. Kelly.—J. S. Purvis.—E. P. Alexander.—Beeching and Goose.—E. F. Hitchin.—R. Pattison.—Historian.—Feed Pump.—Harry Bhill.—Lecturer's Assistant.—R. Stafford.—S. G. Bryant.—Gas Lamp.—Brine.—Ditton.—Saint Rollox.—Garm-Hawa.—E. Hall.—W.—American Organ.—R. A.—Engineer Jack.—S. Bottone.—T. G. Elger.—Bossi.—H. A. Wassell.—J. H.—W. F. Denning.—W. G. P.

A. B. (You will most likely get nitrate of soda of dealers in chemical manures in Dublin, or of drysalters. It is sometimes called cubic petre. If not, those who advertise chemicals in our columns would no doubt supply you. The nitrate of potash or saltpetre ought to be as efficient for your purpose.)—CLERK. (See list of Back Numbers on Copying Processes. One kind is made of glue 1, glycerine 4, whiting to colour, and water sufficient.)—BROTHER STIGGINS. (There is the telegraph service, electrical engineering, and electro-metallurgy.)—ALFRED WATKINS. (The price will depend on what the law stationers like to charge; but we believe that a complete set costs about a shilling.)—MECHANIC. (We cannot give any further advice. Better consult a medical man. All that can be said without seeing you you will find in Vol. XXXIV.)—ANOTHER AMATEUR DADDY. (You will find papers on boot and shoemaking in Vol. XXXVI. pp. 112, 116, 137, 160, 186, 206, 227.)—DOUGLAS. (You will find the information required on p. v. of the number for Jan. 4 last!)—ACIER. (It is said that nitric acid will produce a black spot if dropped on steel—the darker the spot the harder the steel. If dropped on bright iron the metal remains bright.)—X. Y. Z. (The *Transactions* of the Institution of Naval Architects are sold by Sotheran and Co., 36, Piccadilly, W.; but the office of the Institution is 5, Adelphi-terrace, W.C. With regard to the other matter, if you refer to p. 365, Vol. XII., you will find a review of "The Life of Isambard Kingdom Brunel," by Isambard Brunel, published by Longmans in 1870. Your bookseller has misled you. It is useless to specify any date for an answer to appear. As a matter of fact, the number for the 11th was half-printed when your letter reached us.)—COMPARISON. (A query of a similar kind was inserted on p. 331, No. 52481. The Insulite Battery was illustrated on p. 282, last volume.)—G. H. M. (Unless you say what sort of an alarum you require, we can only refer you to the indices. We have given quite a variety. You will want a battery and a bell, and presumably a clock, if it is to wake you up in the morning; but if that is so, why have an electric alarum?)—LITHO. (Both indiarubber and guttapercha solutions are made by dissolving in either bisulphide of carbon or mineral naphtha. The sample sent is guttapercha tissue, largely used by artificial flower makers for wrapping round the stems. That is not produced by a solution.)—DURHAM. (We do not know of such a book; all that can possibly be written about it would not make more than, say, a couple of our pages. You will find all necessary information on pp. 36, 238, Vol. XXXIV. 2. There is a paper called *Hardware*, price 4d., published by W. Leicester, 29, Bow-lane, E.C.)—ESSENTIAL OILS. (Any manufacturer of such apparatus would show you the most suitable still. Fairly complete directions in such books as Ure's Dictionary. You know, we presume, that success can be attained only when they are prepared on the large scale.)—F. SHAW. (The wet; but opinions differ. You can judge for yourself by studying the illustrated descriptions given on p. 466, Vol. XXIX. (wet), and p. 338, Vol. XXX. (dry). The wet meter is liable to freezing.)—WIRRY. (It is impossible to understand, from your account of where the ends of the wires come, what is your difficulty; but all that you need attend to is to see that the wire coils in one direction. Coil some string round a piece of cane, and then bend it to represent the two poles, and you will see at once. The ends can be where you like.)—DR. E. H. BRICKELL. (We think you cannot compel the purchaser to complete the bargain, as no time limit was named, although if your account of the transaction is correct, you have been unfairly treated.)—PRUDENCE. (Yes, if the premises are not damaged by their removal.) B. (1. Must ask through the "Address" column. 2. You are liable for the duty.)—W. L. LANCASTER. (We regret to seem disobliging, but really cannot engrave blocks merely that the individual querist may know whether his observation of the positions of the satellites was a correct one. The positions might have been stated without a sketch.)—TEN YEARS' CONSTANT READER. (Clockwork would, we think, be best, because of the uncertainty attending electricity, which, in your case, would be awkward if the stoppage were ever so temporary. Any clockmaker would devise a plan, but we cannot recommend one here. A sixpenny advt. in the "Wanted" column would probably place you in communication with one.)—T. J. O'CONNOR. (We have not seen the book.)—ENGINEER. (You can sue them at your local county-court; you will only have to state the circumstances to the registrar and obtain his permission to issue the summons. Issue a summons "under Section 1," and you will, we expect, quickly get your goods or your money returned.)—CYPHER. (We do not think you could patent such a thing, and if you could, we do not see how you could enforce it. You could, of course, appoint an agent as you suggest; but what is to prevent him making a similar bread, and selling it without paying you royalty?)—W. B. (As it is so persistent, it must be some kind of skin disease—as a rule, very troublesome complaints. From your description it would seem to be advisable to try change of diet, exercise in the fresh air, and anything likely to increase the strength.)—W. B. (There are machines of the kind, but they are little known out of the factories. Try some of those machinists who lay themselves out for work of the kind, or, if that is impossible, send a more definite query, saying exactly what is meant.)—RAYMOND JONES. (You must have a frame of either wood, zinc, or iron, and preferably a slate bottom. A variety of recipes for cements on pp. 459, 481, 599, 623, Vol. XXXIII. 2. Most likely they have been killed by damp or cold, as they require to be kept growing on. It is only the old plants which will stand frame treatment.)—DE MCGLASGOW. (The usual plan is to rub a coloured powder through the perforations. The pad you refer to was no doubt supplied with aniline ink, like those used for rubber stamps. Look up the subject in back volumes.)—JOHN ROBERTS. (You will find an article on the subject in Vol. XXXI., p. 57, and others in previous volumes.)—CHEMICUS. (Several motors of the kind described in back numbers, and series of papers on the subject now in course of issue. Look up the indices, and then you can select the one you think will suit you best.)—H. B. (You should have used gas tar and lime, not Stockholm. If chimney gets red hot, nothing stands well, but perhaps blacklead mixed with stale beer looks best and lasts longest.)—O. H. M. (What speed do you expect to get? The arrangement proposed would do as well as anything else; but see what has been said in back numbers about electric launches.)—WAYMAN. (If recent, try oil of turpentine, fuller's earth, or even strong solution of soda. If old, make a paste of fuller's earth and soft soap, with a little turpentine and lay on; but as a rule they can generally be removed with pieces of blotting paper and a warm iron.)—UNEMPLOYED. (The actual knowledge required is very small; but some little practice is necessary. Both men and women are employed.)—C. R. (See p. 118, Vol. XXXIV.; p. 544, Vol. XXXIII.; and the indices generally.)—H. F. H. (The stone must be roughed down with a chisel, or, if round, with a tool in the lathe. It is then brought to a smooth surface with sand or emery and water, using wood rubbers, and then polished with tripoli, &c.)—JOHN A. REKOE. (See p. 580, last volume, and many other places in recent volumes. There are several processes and many little secrets.)—MASSEY BROWN. (For frosting tin, see pp. 202, 225, this volume.)—PHOTO. (See pp. 490, 513, Vol. XXXII.; but the process is given in all the handbooks. 2. The best developer is usually given by the makers of dry-plates; but you will find one suitable in some of the back numbers.)—AMATEUR. (It would not be an advantage, because that metal rapidly loses all magnetism.)—SUBSCRIBER. (The best anti-incrustant depends on the nature of the water. Try common washing soda. See p. 114 last volume, and pp. 215, 261, this volume. About ½lb. of soda put into feed-water would be a sufficient daily dose for such a boiler, even if the water contains much carbonate of lime.)—ARIEL. (Mr. Fletcher, Warrington, makes just the sort of furnace you require; but what is meant by "iron, &c."? However, see his catalogue.)—NO NAME, Derby. (No, not with plenty of practice. 2. They may be described as half-round valves, revolving in passages instead of sliding over seats. 3. It is a matter of opinion.)—IMPUDENT TELEGRAPHIST. (If "cement" was mentioned, no doubt electrical cement was meant—viz., rosin 5 parts, beeswax 1 part, and red ochre or Venetian red 1 part. Some add plaster of paris or whiting.)—JNO. PARSONS. (The description is not sufficiently technical.)—DR. E. S. HABEL, St. Louis. (For the present, further particulars must be looked for in Specifications Nos. 5122, of 1882, and 1639, of 1883.)—C. MATHERY. (You do not give us any clue to the previous answer, nor even state what numbers were wanted, nor the subject on which information is required. If the numbers are out of print, a query is usually inserted. The list referred to is inserted the first week in each month, or "at intervals," as plainly stated in its heading.)—W. ROBERTSON. (The lower end of a barometer tube is immersed in a small cistern of mercury, and is not "sealed airtight." Consequently, the height of the column of mercury is a measure of the pressure of the atmosphere.)—W. J. L. (See p. 256, No. 789. It is a patent, and you would find full details of all the processes at the Patent Office Library, if you cannot refer to our back volumes.)—STRATHEDEN. (Probably some of the lenses have shifted; but it needs examination to point out the remedy.)—AMATEUR MOULDER. (You will find two brass melting furnaces on pp. 120, 240, Vol. XXXIV., and several others in back volumes. If you have gas, procure Mr. Fletcher's catalogue from Museum-street, Warrington.)—M. H. D. (There is no book that gives such details as you require. You will find them in a series of articles in these pages, and also in back numbers.)—V. DE V. (No examination is necessary to enable you to call yourself "C.E." There are examinations held by the Institution of Surveyors, Great George-street, S.W. The secretary would probably send particulars on application. Twelve months in a good London office is what you want; books will be of little use; but some good and cheap manuals are published by Lockwood and Co., 7, Stationers' Hall-court, E.C.)—R. A. BENNETT. (Impracticable; the number sold would not pay. You probably forget that a very small minority, comparatively speaking, have a *complete* set.)

AND WORLD OF SCIENCE AND ART.
FRIDAY, JANUARY 25, 1884.

ELECTRIC LAUNCHES.

UNDER the title of "Electric Launches" an interesting paper was read by Mr. A. Reckenzaun, before the Society of Arts last week, and, as might be expected, a businesslike discussion followed. It is obvious to those who give a moment's thought to the subject that if electricity can be economically used for propelling launches, it will speedily take the place of steam; for even if it costs more, the advantages are so great that any moderate increase in the expenditure will be cheerfully paid. In the first place, in a steam launch a very large portion of the boat is occupied with the engine and boiler, which, almost as a matter of necessity, involve smoke and dirt, and do anything but add to the comfort of the passengers; in the second place, in a steam launch the risk of accident is much greater than it would be if electricity were employed as the propelling agent. If a vertical boiler is used in a launch the tendency to upset is increased; if a horizontal boiler is employed a much larger portion of the total carrying space is taken up by the machinery. In an electric launch, on the other hand, the driving engine, the dynamo, occcupies a very small space comparatively, and the power generators, or immediate source of the energy, can be stowed away in the corners and arranged alongside the keel—thus not only leaving all the available space for the use of passengers, but also increasing the stability of the craft, by keeping the weights low down. Electric launches are, however, not a modern invention, and it therefore follows that there is some sufficient reason why they have not been brought into general use—a reason which will be found in the single item, expense. So long ago as 1838 Prof. Jacobi drove a boat by means of a primary battery and an electro-magnetic engine; and somewhere about 1850 an electric launch was tried on a lake at Penllegaer, near Swansea, under the direction of Mr. Hunt and Sir William Grove, who were the designers of the boat and machinery. Several other experimental trials are on record, but until Trouvé in 1881 started his boat *Eureka* on the Seine, the expense of working electric launches was practically prohibitive. The improvements in the dynamo effected by Gramme and Siemens have, however, brought the question again prominently to the fore, and the point to be decided now is whether the primary or the secondary battery is the cheaper source of energy, all things considered, as applied to the work of driving an electric engine. According to Mr. Reckenzaun, the cost of steam, secondary and primary batteries, is respectively 1, 2·5, and 12, which, on the score of expense, puts the ordinary zinc battery practically out of court. But other points besides those of mere cost of materials have to be considered, and it is probable that, after all, many persons would prefer the primary battery. So far as we know, for we are not familiar with the secrets of certain wonderful new batteries, there is no cheaper source of energy in the cell than the consumption of zinc, and as that costs in quantity about 3d. per pound, and two pounds yields an electrical horse-power per hour, it is easy to calculate the expense of that item in an electric launch. To take Mr. Reckenzaun's figures, the cost of zinc alone to drive a launch with five electrical (or four mechanical) horse-power, would be 2s. 6d. an hour; but to that must be added the cost of the acid or other exciting fluid, and also the value of the time expended in charging the battery. What with cleaning, amalgamating, mixing the solutions, and refilling a battery capable of doing six or seven hours' work at the rate of five electrical horse power per hour, one man would find plenty of occupation for a whole day, even with the best appliances; but the same amount of labour might be expended on a 6-horse steam-engine, and a dynamo for charging 50 accumulators, each of a capacity of 370 ampère hours, or one horse-power hour. That would give nominally five horse-power for ten hours; but it is never advisable to run a secondary battery right down, so Mr. Reckenzaun takes seven hours as the duration, and reckons the cost at 2s. 9d.; whereas the cost of zinc alone, in a primary battery supplying two electrical horse-power for seven hours would be 17s. 6d. It is not quite clear how the 2s. 9d. is calculated, but it is Mr. Reckenzaun's estimate, and obviously leaves out the interest, wear and tear, and other items, in connection with a steam-engine and boiler and a place in which to keep them—the cost of the dynamo and the two kinds of battery may be considered equal. Mr. Reckenzaun points out that it is hardly likely that any one will lay down a complete plant for the sole purpose of charging the cells of one boat, and, therefore, in order that electric launches may be useful, it will be desirable that charging stations should be established. A system of hiring accumulators will, as he says, best satisfy the conditions imposed in the case of pleasure launches; but it must not be forgotten that the duration of any trip is limited by the time during which the accumulators will give out energy, for it will not always be convenient to wait while the secondary battery is being re-charged, nor altogether feasible to replace the exhausted cells by others, which may be kept in stock ready charged. So far as pleasure launches are concerned, then, it is probable that the primary battery will at least meet with as much patronage as the accumulator, unless, indeed, someone devises a method of re-charging in as many minutes as the cells will last hours.

Mr. Reckenzaun's data in connection with secondary batteries may be useful. A Faure-Sellon-Volckmar cell weighs 56lb., stores energy equal to one horse-power for one hour, or 1,980,000 foot-pounds, or, say one horse-power per minute for each pound weight of the cell. The charging capacity is as much as 370 ampère hours, but it is not advisable to use more than 80 per cent., or 300 ampère hours. If the cell is discharged at the rate of 40 ampères, an almost constant current is obtained for 7½ hours, with an E.M.F. of 2 volts. If one horse-power is required for that time and at that rate of discharge, more than nine cells are wanted; but 47 cells will supply five electrical horse-power, and will weigh 2,632lb. About half the number of cells discharged at a rate of 80 ampères will supply the same quantity of energy, but only for less than half the time; or the 47 cells can, if desired, be made to give ten or twelve electrical horse-power for over two hours. To the weight of the battery 2,632lb. has to be added, that of the motor, which need not weigh 400lb., says Mr. Reckenzaun, if economically designed, and which will give four horse-power on the screw-shaft. Allowing a margin for leads, switches, &c., the total weight is about 28cwt., which Mr. Reckenzaun says is equivalent to that of an equally powerful steam-engine with the maximum stowage of coals. The launch sent to the Vienna Exhibition, which made many successful voyages on the Danube, is of steel, 40ft. long and 6ft. beam, with seats to accommodate 40 adults. The motor is capable of working up to seven horse-power with eighty accumulators, but with the exception of a slight rise just above the motor, the floor is quite clear, the accumulators and engines being beneath, out of sight. In such a launch driven by steam-power, the engine and boiler would occupy a length of 12ft., leaving only 15ft. available for seating passengers, whereas the seating capacity of the electric launch is 27ft. on each side of the boat; or, in other words, the steam launch would carry only twenty-two passengers to forty in the electric launch. The relative weights of machinery are about the same—viz., 50cwt., but in the case of the steam launch that includes 10cwt. of coals, which at 8lb. per i.h.p. per hour (7 h.p. actually given to the shaft) would allow of fifteen hours' continuous steaming, or just double the time that the launch could travel without injuriously drawing on the accumulators. The present accumulators yield 33,000 foot-pounds per pound of lead. Theoretically, lead separating from its oxide manifests energy equal to 360,000 foot-pounds, while the figures for iron are 1,900,000 foot-pounds. It is evident, then, that although nothing like those figures can be reached, there is a very large margin for the future advance of inventors with secondary batteries; but it is doubtful whether much more can be done with the motors, especially as Mr. Reckenzaun exhibited one of his inventions, just finished, which with a weight of 124lb. yields 1·37 mechanical horse-power, running at 1,550 revolutions, and giving 31 ampères and 61·5 volts. at the terminals. In connection with electric launches, the old debates as to the efficiency of the screw propeller are likely to be reopened, for in them the propeller is fixed on a prolongation of the motor shaft, and it consequently revolves at a very high speed. According to Mr. Reckenzaun, a fine-pitched propeller he exhibited gave an efficiency of 95 per cent. when running at 800 revolutions per minute. In the course of the discussion that followed the reading of the paper, it was pointed out that it was a fallacy to suppose that slip in itself was a loss, and the 5 per cent. lost by this propeller did not give any idea of the efficiency. To that Mr. Crohne (of Messrs. Yarrow) replied that such a pitch, about 10in. to a diameter of 20in., was unknown before, and he had been of the opinion that it would not do at all. He expected that negative slip and friction of the propeller would make a serious impediment; but when the experiments were made he found he was entirely mistaken. Mr. Reckenzaun said that the propeller was designed to run at 900 revolutions; and that if the speed were reduced to 300, not only would the pitch have to be altered, but the surface would have to be larger, which would entail more friction. The performance of this propeller is, in fact, a revelation, and it is to be hoped that before long some experiments will be made on a larger scale in steam vessels. The number of strokes made per minute by the pistons in fast-steaming vessels ranges from, say, the 133 of the *Stirling Castle* to about 1,000 in some of the torpedo boats; but as revolutions of the screw is the point to be studied, it will be seen that the electric launch is far ahead of anything known in connection with steam-engines. Admiral Selwyn commenced the discussion by suggesting that electrical propulsion would be specially applicable to lifeboats; but if that is to be so, some new form of battery will have to be devised, for, as a matter of fact, the electric launch is literally "at sea" when it gets into rough water, owing to the spilling of the acid solution. Admiral Selwyn also created some interest, not to say excitement, by stating that he had seen one-sixth of a pound of fuel producing one horse-power; and when challenged, he proceeded to give his idea of how it was accomplished. But as, so far as we know at present, such an economy is simply impossible, we may well [illegible] take care of itself. A [illegible] was the inquiry [illegible] Reckenzaun as to the cost [illegible] shown at Vienna. [illegible] by the answer [illegible] though it drew [illegible] the remark that if the [illegible] required to run con- [illegible] accumulators would be [illegible] the discharged set could be [illegible] another which he thinks could be [illegible] in a few minutes. [illegible] may be taken that a secondary [illegible] run down in seven hours, [illegible] seven hours in charging. [illegible] Mr. Preece, who had asked [illegible] the cost, stated that he [illegible] Vienna it was about £800, [illegible] was a little too much for [illegible] he has a strong faith in [illegible] batteries, and believes that before [illegible] will discover how to render [illegible] a launch even in [illegible] to the accounts, [illegible] battery p. 407) is [illegible] and will stand a good [illegible] and no doubt Mr. [illegible] devise a means of [illegible] but at present [illegible] been subjected to any- [illegible] than the shaking re- [illegible] alongside the tugs on [illegible] the electric launches [illegible] except in what is practi- [illegible] water. As to the question [illegible] is not damaged [illegible] formation of a film of [illegible] Mr. Reckenzaun stated [illegible] considerably reduce the [illegible] as it was broken [illegible] give off its maximum [illegible] constructed ac- [illegible] difficulty in getting [illegible] of the energy put [illegible] Reckenzaun; but he [illegible] be a long time before [illegible] What is wanted is the [illegible] exhausting coal itself [illegible] much of the [illegible] wasted in the furnace. [illegible] until some such dis- [illegible] will vessels be [illegible] by electricity [illegible] fifty years old, and [illegible]

[illegible] NOW MADE AND [illegible] USED. XII.*

[illegible]

[illegible] necessary to clamp to [illegible] standard, or bracket, [illegible] wheel to the two [illegible] At the concluding [illegible] to the advisability

[illegible] right through the top [illegible] at the same time [illegible] drilled in the same [illegible] indicated [illegible] in [illegible]

diameter, and the two lower ones should be at least ¾ of an inch from the bend of the flange, so as to allow the nuts to be easily turned and tightened up. These two bottom holes should be about 2in. apart, while the upper one should stand equidistant from the others, but at about ½ an inch from the top of the flange. The amateur will find at any of the good furnishing ironmongers, very neat skate screws with nuts to fit, of the form illustrated at Fig. 22. These screws have usually rounded heads, without the slot for the screwdriver to enter: but these can be easily cut with a metal-saw. Of course, any small bolts and nuts having a section of about ¼in. will do, but the ones mentioned are very neat in appearance. The holes being drilled and the bolts and nuts chosen, the bracket and limbs of the field magnet may be temporarily clamped together, in order to see what opening is left between the legs for the armature to turn in, at *a*, Fig. 23. In all probability some filing of the faces of the flanges and of the bracket will be necessary to insure a proper fit. A well-fitted armature should, if placed in the centre of the channels at *a*, leave a space of a trifle more than 1/32 of an inch to turn in: that is to say, there should be rather more than 1/16 of an inch clear space all round between the armature and the field magnets. Perhaps the quickest way to insure this distance being obtained is to roll tightly a single fold of stout brown paper round the armature and seal down the edge to prevent it slipping; then, having inserted the armature in the channels, to file away at the inner faces of the flanges, either towards the lower portions at *b b*, if the channels are too wide apart, or at the upper extremities at *c c*, if too close, until the whole fits accurately together. It is as well to remark that when the armature thus wrapped in paper is placed between the field magnets, to obtain a correct fit, *the solid portions of the armature should lie against the legs*, and *not* the portion of the armature which is hollowed out for the reception of the wire (see Fig. [illegible]).

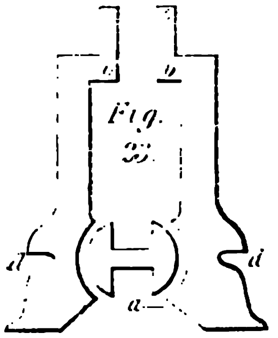

Fig. 23.

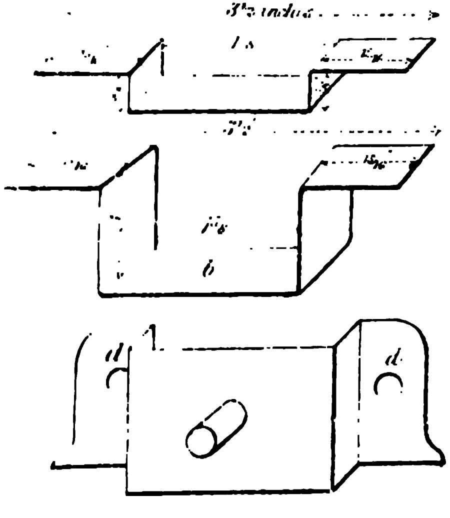
Fig. 24.



The magnets and brackets being thus properly clamped together, the hole in the top of the bracket (which ought to have been left in the casting, but if not may be bored now) should be cleaned out to ¼in. diameter. When this is done, two pieces of hard rolled brass sheet ⅛in. thick, 6in. long by 1in. wide, must be [illegible] squared up. One of these, which we shall for the future call the "back bearing," and which is to be made to fit that end of the dynamo at which the driving wheel is to be placed, and which we shall henceforward call the "back" of the dynamo, is to be bent four times at right angles, as shown at Fig. 24 *a*, where the dimensions are given. In order not to crack the brass when bending to shape, it will be well, after having given the general form by bending gently and gradually over the jaws of a vice, to heat the bends over the flame of a spirit lamp until nearly red hot, and then to hammer up more exactly to shape, repeating the heating after each hammering until the desired sharpness of outline has been obtained.

When this object has been attained, another almost similar bearing is formed out of the remaining piece of sheet brass, the principal difference being that, as this is to be the front bearing, between which the commutator will have to turn, a much greater depth must be given to the central bent portion, as may be seen at Fig. 24, *b*, the dimensions being given in inches as before. When the brass has been bent to these forms, the bearings thus produced should be laid each against its own respective end of the dynamo, in such a position that the centre of the bend comes in the centre of the channel, the two flat extensions lying close to, and flat against, the slotted lugs shown at Fig. 23, *d d*. The bearings should now be cut in a sloping fashion to follow the outline of the lugs, as shown at Fig. 24, *c*; but the outline of the slotted portion should not be followed, as a ¼in. hole must be drilled in the brass at this point to take a ¼in. bolt and nut. The exact position of these holes may be obtained by holding each bearing in succession against its own proper extremity, and scratching with a steel point on to the brass the position in which the slots in the lugs fall; then with an Archimedean drill, a ¼in. hole can be drilled at each extremity *nearest* to the centre of the bearing, as shown at Fig. 24, *d*.

Having got so far, let us clamp the back bearing in its place by means of two bolts about 1in. long, passing through the holes in the bearing and through the slots in the lugs, held in their places by two nuts screwed down on to the front lugs of the dynamo. Taking the armature in one hand, we roll, as before, one fold of paper round it, and put a dot of Brunswick black on the extremity of the trunnion rod at the back end of the armature (the end where the holes are bored for the wire to come out is the front, the other is the back), and then insert it into the channel between the legs of the field-magnets, until the trunnion rod or shaft touches the brass forming the back bearing. In so doing it will leave a mark of Brunswick black, which will be the point at which a ¼in. hole must be bored. This must be done most carefully, so as to preserve centricity; and when done must be rimed out and bushed with a piece of brass tubing of about 5/16 external diameter, the internal diameter of which must exactly correspond with the external diameter of the driving-shaft or trunnion of the armature: in fact, this latter must fit exactly into the tube, without any shake. This piece of tubing should be about 1¼in. in length, and should be soldered into the central hole in the back bearing, and should extend inwards to such a degree that when the back bearing is clamped in its place, with the armature in its position, with the back trunnion in the tube, and the back head flush with the back of the magnets, it should just rest against the back head of the armature.

In a precisely similar manner the centre of the front bearing is found: that is to say, the back bearing being removed, the front bearing is clamped to the front of the dynamo, the armature, rolled in one fold of paper, is inserted from the back end of the dynamo, front end forwards, and care taken to moisten the front end of the driving-shaft with Brunswick black or other colour, so as to get a mark where it touches. The hole being drilled and rimed out, as in the previous case, is to be likewise bushed with the same kind of brass tubing, but, in the front bearing, the tube should be only flush with the inside of the bearing, and should not extend in towards the armature.*

---

* To those who prefer fitting together the finished castings, to making every part themselves, I feel much pleasure in recommending the castings advertised in our columns by Mr. H. Jones, who has submitted some to my examination, which I find fully in accordance with my instructions.

PRACTICAL NOTES ON PLUMBING.—XCII.*

By P. J. DAVIES, H.M.A.S.P., &c.

(*Continued from p.* 402.)

Hot-Water and Gas Work and Fitting.

WE have now come to that part of our work which is often discarded by the plumber as being beneath his notice, and by those who cannot do this class of work, as being something out of the trade; but the fact is, that our best hot-water work is generally, as it should be, left to the *qualified* plumber.

We will presume that you are thoroughly acquainted with the laws which govern fluids; but there is one law which we shall have occasion to draw your particular attention to, that is, the law of heat when held in these fluids, for without a knowledge of such law, it would be useless to attempt hot-water work unless it be by rule of thumb work only.

Every one is familiar with the fact that when their hand, if of a different temperature, is applied to a hot or cold body, that the *hand* is readily made sensible to the fact, and according to the difference in the temperature so will the amount of sensation be felt. This is one way of experiencing the effects of heat. We all know that the heat of the sun's rays is felt by us all more powerfully at one time than another; but we do not all know that the heat from the rays of the sun on a hot summer's day will, on one acre of ground, produce as much steam as could be produced from a boiler consuming at least six tons of coal; and the uninformed do not know that the radiant rays of the sun traverse through space at a velocity of 190,000 miles per second, nor does he know that heat and cold are one and the same, which according to its degree of temperature acts upon the nerves, and which sensation is experienced in strict accordance with the temperature of the applied body.

We speak of heat when this substance (if it be a substance) is in temperature above that of the common air, or the applied body, and of cold when it is below this temperature. There are some bodies which may be considered as capable of absorbing heat, which absorbed heat will reside in such bodies for a very considerable time, and often in a latent state. For instance, the heat in ice is latent, and not perceptible to our senses of feeling. For argument, suppose you place your hand into water, the temperature of which is exactly the same as that of your hand, the heat phenomena cannot be felt, therefore the heat is latent to you. For the same reason ice holds latent heat. Water solidifies at 32°, and will take in or absorb 140 degrees of heat to each pound of ice before it will rise in temperature, or, if I may so speak, feel hotter; and a further 1,000° more heat must be hidden in water before the ice is converted into steam, so that we say that in steam there is 1,140° heat latent, and although we put a thermometer into this steam, it will only register 212°. This is a curious fact, and only goes to prove that which I have before written on this subject, and it is good for us that this is so, for if all the water were suddenly to turn into steam, an explosion would take place every time we boiled a drop of water. I may add that you may keep boiling away at water, and so drive out all the air held in solution, and when such is done you may raise the temperature to at least 360° Fahr.; you are then liable (if the air be absent) at any moment to have an explosion. For my part, I am quite convinced that many of our terrible boiler explosions which have never been accounted for, have been caused by the continual boiling of the same water, which is often the case for days and nights together, and which must drive off the air held in solution before spoken of.

To prove this, take a piece of Wenham ice, and place it in a large test tube, then cover it with turps (turpentine). Carefully melt it, and without admitting the air, make it boil. The heat required will be considerably more than 212°, but as soon as steam is generated the whole of the water will jump out of the tube as though gunpowder were under it.

I have said that the temperature of issuing steam is never more than 212°, but it must not be lost sight of that water may be heated to a very high temperature, according to the strength of the vessel wherein it is held. And when this is done take particular notice that you leave sufficient room in the vessel for the expansion of the water, which will expand when heated from 39·40° (the greatest point of condensation) to 212°, one twenty-third part of its bulk, and if inclosed within a close vessel will exert a power of 14,121lb. on the square inch. It also should be known that water in our common atmosphere boils at 212°, but double the pressure of the atmosphere on the surface of the water, and though this may at first sight appear paradoxical, it will not boil before it has attained 250·52° F., and if your vessel be constructed so as to resist, say, 25 atmospheres of pressure, then your water will not boil until it has attained the heat of 439·34° F.

I may here state that one cubic inch of water will make 1,696 cubic inches of steam, compressed to 15lb. to the square inch. The following may assist you in your reasoning respecting the quantity of this latent heat. You may say that snow is the very essence of cold, but in comparison to the following will feel quite warm. Take two bowls of snow, and put into one bowl half as much common salt. Place your hand into this mixture, and you will be very pleased to withdraw the hand, if only to place it in the bowl of pure snow, which will then seem to be warm, and, of course, the heat not latent. I may add that when mercury is frozen, the mere fact of picking it up with the naked fingers will blister the fingers just as if it were a piece of hot iron. These are simple experiments whereby you will be better able to judge what constitutes the different degrees of heat, latent, radiant, or otherwise.

(*To be continued.*)

ELECTRIC LIGHTING AT THE TRINITY LIGHTHOUSE, SOUTH FORELAND, NEAR DOVER.

SIR JAMES DOUGLASS and several other scientific gentlemen are about to institute a series of electrical experiments on behalf of the Trinity Board, with their existing electric lighting machinery and an enormous De Méritens machine, at the two lighthouses near Dover. Dynamo machines do not appear to rank as the best generators for lighthouses; as Holmes's magnetic induction machines have held their own at this important lighthouse, and, amongst the trials about to take place, a De Méritens large-size magneto generator will be installed, which is expected to yield magnificent results. These machines of De Méritens will soon occupy all the lighthouses on the French coast, and it is a wonder these generators have been so little adopted in this country.

Count du Moncel, in his translated little work, speaks of their high power, as compared with the small force required to drive them. In this machine alternate currents are produced, and the whole of the armature current is utilised during its entire or part revolution. This form of armature also requires but little h.p., on account of the peculiar arrangement of the circular magnetic field it rotates in, on a smaller scale, as in the factory machines, which yield about 1,200 candle-power, at about 750 per minute, and absorb only 1¼ h.p. The small machines contain about 3cwt. of steel inducing magnets, with their poles placed alternately N. and S., which operate upon 16 annular magnets forming a ring tire armature, which are arranged on the periphery of a brass wheel. Each annular magnet contains about 1½lb. of wire, and the iron core is built up of pieces of iron, instead of being solid castings, which heightens the induction effects, and also prevents the formation of injurious Foucault currents. Two brilliant electric lights have hitherto been visible for many miles at sea from the South Foreland Lighthouse; but the experimental installation soon to take place will eclipse the light at present emitted from the two lanterns on the tower. It was from these lighthouses Prof. Tyndall carried out his famous experiments on sound by a fog siren driven by the engines of the lighting machinery.

HOW TO MAKE A CHEAP LATHE.—VII.

The Slide Rest.

THIS is a piece of mechanism which most amateurs who essay metal turning at all desire to possess; but which, nevertheless, few except professed machinists have the courage to attempt, or attempting, have the perseverance to complete. And yet to those who have undertaken successfully the construction of a common lathe, there should be nothing to hinder them from the construction of a slide rest also. Let us, in the course of a half-hour's chat, endeavour to make the matter as simple as possible.

Fig. 85 gives a perspective view of the rest, in which A is the saddle, B the transverse slide, C the longitudinal guide, D the tool-holder, E the screw handle for transverse movement, F the handle for longitudinal motion.

For these, plain patterns will be wanted. That for the saddle, Fig. 86, will differ from the casting in these respects only. The holes for the traversing screw will not be cast in. A slight allowance for fitting must be made on all working surfaces—a full 1-32in. if we are going to fill up our castings, a bare $\frac{1}{8}$in. if it is intended to plane them. The two dovetailed shaped strips *a a* will be left loosely wired on, to be drawn into the mould after the main body of the pattern is lifted out, and the interior nut recess will be cored out. Fig. 87 represents the wood pattern in section, Fig. 88 its core box. The pattern of the transverse slide, Fig. 89, will also have its dovetailed strip left loose. The remarks made relative to the saddle will also apply to the longitudinal guide, Fig. 90. In fact the saddle pattern may be altered for the guide by removing the base which slides on the lathe bed and substituting for it the circular foot *a*. Two sweeped prints and a core box to match Fig. 91 are wanted for the slots, by which a limited spherical movement is given to the tool. A pattern for the movable slides, Fig. 92 *a*, and also one for traversing nuts, Fig. 93, will complete this part of the business.

We begin our fitting at the saddle, and travel upwards. And we assume as before that a planing machine is not available. File the under side of the saddle accurately, using winding strips and surface plate, and following the instructions and hints given relative to the filing of the headstock castings in Art. III. Operate on the upper face in a similar manner, and check with calipers to insure perfect parallelism. Make a metal templet, Fig. 94, to the angle of the slides, about 60°, and file one edge straight to this templet, and at right angles with the timbers of the bed, checked with a square not less than 10in. or 12in. in length, held against the saddle when the latter is in position. Scribe the opposite edge parallel, and file that until a second templet, Fig. 95, can be slid from end to end and bear with equal pressure on every section. File the ends square, and for appearance sake brighten up the remaining parts of the saddle.

Drill the holes, two for the traversing screw, one for the hold-down bolt. If you still presume on the kindness of your friend who allows you to use his lathe, you will bolt the saddle to the angle plate, and hold your drill in the slide rest, as when boring the hole for the back centre of the headstock, Art. 3. But you can do the same as I did—fit the parts of the rest in your own lathe, using the drill chuck and plate for these holes. Taking the drill plate, I screwed thereon a squared cubical block of wood in such a position that with the face of the saddle laid against it, the centres of the holes for the screw coincided with the centre of the lathe. It stood out sufficiently far—about $4\frac{1}{2}$in.—to insure steadiness longitudinally; in fact it was an improvised angle plate for temporary use. The hole in the front of the saddle will be drilled to $\frac{5}{8}$in. diameter, that in the back to $\frac{1}{2}$in. The one for the hold-down bolt will be the same as for the headstocks, $\frac{5}{8}$in. tapping.

We go on with the filing business, leaving the long screws and nuts until the last. Take the next casting in ascending order—the transverse slide, Fig. 89. File the face and one edge, the one marked *a*, true, also the sliding face parallel with the first. Make a metal templet, Fig. 96, just the reverse of that shown in Fig. 94, and use it as a gauge for filing the bevelled edge *b*, taking a large three-corned file for the purpose. Take pains with all these sliding faces, and finish in every case with the scrape.

File the adjustable slide C to thickness, drill and countersink two 5-16in. holes as shown, set in position, allowing a little for filing off the bevelled edge, and drill and screw two corresponding holes in the transverse slide, using ordinary stove screws to secure the adjustable piece in position. Mark the ends of the loose piece with metal templet, remove, and file to a

[illegible] with the saddle [illegible] the loose [illegible] the accuracy of [illegible] the edges, d, e, f parallel [illegible] with the [illegible] through the exact centre of the [illegible] for the reception [illegible] of which more anon. Two [illegible] for the reception [illegible] the transverse [illegible] the upper guide for longitudinal [illegible] capable of limited [illegible] the edges with [illegible] fashion as the [illegible] in the ends [illegible] face upon the [illegible] and the edge of [illegible] exactly through [illegible] slots with files, [illegible] from the edge of the

[illegible] slide and tool box, Fig. 92. Precisely the same routine is to be observed as in the transverse slide. Instead, however, of the two screws for spherical movement, we have four for the purpose of tightening the tool. Over these studs two plates of wrought iron, *a a*, are slipped and held down on the tool by the nuts. If you choose, you may make four springs to keep the plates just under their nuts, and so avoid the slight trouble of lifting them up when it is desired to slip a tool underneath. Get a bit of 1-16in. hard brass wire, wind it round a ½in. bar about half a dozen times, cut off, and slip over tightening screw. When each screw is thus provided with its spring, drop the plates and nuts finally in position.

Two traversing screws precisely alike, Fig. 97, will be required. They are made of ⅝in. rod, collars being welded on. Skim over in the lathe, turn the collars, and screw—preferably in the lathe—or, failing that, with stock and dies. The ½in. screw at the end is for the lock nuts, *a a*, and the turned portions, *b b*, run in the holes drilled in the castings, Figs. 86, and 90. The square part is for the handle.

For the handles get a couple of forgings or brass castings, made to Fig. 98. File the square holes to fit over the square ends of the traversing screws. Drill a 5-16in. hole at *a*, into which rivet handle *b*, turned out of a bit of ⅜ rod, or of brass.

Turn the shoulder of the nut square, and cut a ½in. thread, Fig. 93, *a*. In one nut, the one fitting into the tool slide, the screw will be ¾in. long, thus terminating on the upper face of the slide. But in the other case the screw will be an inch long, and the ¼in. which projects above the face of the transverse slide will be turned to 7-16in. to fit the hole in the longitudinal guide, Fig. 90, and the guide will swivel round upon this.

Drill a hole and tap a ⅝in. thread to fit the thread of the traversing screw, keeping the centre of the hole at exactly the same distance from the shoulder of the nut as the holes in the saddle and the longitudinal guide, Figs. 86, 90 are from their faces.

Provide the saddle with a hold-down bolt like those made for the headstocks, Art. V. Put all parts together. Remove the adjustable slides, screw in the brass nuts, slip the slides into position, with the nuts within their spaces, run in the traversing screws, and finally screw on the adjustable pieces. If the slides wear in the course of time, a few strokes of the file over the top face of the loose pieces will insure a close fit again.

About the cost. The castings weigh 18lb. at 2d. per lb. = 3s. Brass nuts and handles, 1¼lb. at 1s. = 1s. 3d. Screws and nuts, say, 2s. Total, 6s. 3d. Seven shillings will cover cost for material. So that our account stands thus :—

			s.	d.
Art.	I.	Castings	15	0
,,	II.	Timber	10	0
,,	V.	Sundries	15	0
,,	VI.	Chucks	13	0
,,	VII.	Rest	7	0
			60s.	0d.

For three pounds, then, we get a lathe and accessories that could not be purchased for ten. It is the growth of many hours of labour—to me of labour *con amore*. Its description, now concluded, has been a pleasurable task, and I trust many of my fellow mechanics will thereby be induced to construct one for themselves. Turning, sawing, drilling—it will execute these operations with ease. The little saw would be simply invaluable to many home-workers, as also the drill chuck. Many an hour have I laboured, before I had a lathe, in drilling small holes with a common brace. By means of the drill chuck and plate I can now drill much larger holes without one-tenth of the labour formerly necessary. Available also for almost every description of ordinary light turning, it becomes in the wide range of its operations a *useful* as well as a *cheap* lathe.

THE CHISEL AND CHISEL-SHAPED TOOLS.

THE first day I entered the machine-shop I was given a hammer and a cold chisel wherewith to chip the ends of some bolts level. I had looked forward to my entry into the shop with a great deal of pleasure, for my heart and mind were set upon becoming a skilful workman. The idea of being able to cut and shape metal to my will, and form it into the machines that were to save mankind the exercise of mere brute force, had such a charm for me that it was the height of my ambition. An apprentice of some two years' standing was to show me how to use this chisel, which he did as follows: "You hold the chisel so, and the hammer so, and then you chip this way," and he cut off the end of the first bolt very nicely and quickly. I tried to follow him, but after the first blow, which by chance struck the chisel-head sideways, I became aware that my hand was dangerously near to the chisel-head. I realised this more thoroughly at the second blow, for the hammer fell upon my thumb, to the great amusement of my neighbours. After that I could not be persuaded to hold the chisel near the head unless I held the hammer pretty close to its head, so that I could take better aim. For two days I struggled on, left to myself to find out by bungling along how to grind the chisel, and all the other points that could have been taught me in an hour. What was worse, I became disheartened, for instead of finding all plain sailing, with nothing to do but to master the principles of tool using, feeling every day that I had made some progress, I found myself floundering in the dark, not understanding anything of what I was doing, asking others to grind the chisels because I had no idea how to do it properly myself, and at the end of the first month I should, but for the authority of my parents, have tried some other business. The machinist's trade seemed to be nothing but one-half main strength, one-quarter stupidity, and the other quarter hand skill that every man had to work out for himself, for no body seemed able to help me. Many a boy meets just this same experience, and getting discouraged drifts about a month at this trade, two months at that, until he finds himself at last without any trade at all, and very often in his old age without the means of earning an honest livelihood. Examples of this kind are, I believe, within the personal knowledge of most of us, and the fault is often attributed to the absence of an apprenticeship system, but if we go deeper I am persuaded that it will appear that it is more in the want of intelligent preparation for the workshop.

Parental authority, as I have said, saved me from this misfortune, but since then I have, in the course of years, mastered the principle involved in the use of this cold chisel, and I can now draw you two pictures, which I hope will not be uninteresting. Suppose when I went to the shop doors to ask f employment the superintendent said to me, "We to be a machinist, do you? Well, why do think you are fitted for it; do you know any

* A lecture delivered by JOSHUA ROSE, M.E., before the Franklin Institute, Philadelphia.

about it, or about tools? On what foundation have you built the opinion that you will ever make a good machinist?" What could I then have answered, except that I thought so, hoped so, and meant to try my best. But suppose I was again a boy, and again found myself at the shop door, having previously taken enough interest in mechanics to have remembered the principles I had already been taught, I could take a pencil and a piece of paper and answer him thus:—

I can only say, sir, that I have prepared myself somewhat for a trade; here, for example, in figures 1 and 2 are shown the shapes in which flat chisels are made. The difference between the two is that, as the cutting edge should be parallel with the flats on the chisel, and as Fig. 1 has the widest flat, it is easier to tell with it when the cutting edge and the flat are parallel, therefore the broad flat is the best guide in holding the chisel level with the surface to be chipped. Either of these chisels is of a proper width for wrought iron or steel, because chisels used on these metals take all the power to drive that can be given with a hammer of the usual proportions for heavy clipping, which is—weight of hammer, 1¾lb; length of hammer handle, 13in.; the handle to be held at its end and swinging back about vertically over the shoulder.

If I use so narrow a chisel on cast iron or brass, and give full-force hammer blows, it will break out the metal instead of cutting it, and the break may come below the depth I want to chip and leave ugly cavities. So for these metals the chisel must be made broader, as in Fig. 3, so that the force of the blow will be spread over a greater length of chisel edge, and the edge will not move forward so much at each blow, therefore it will not break the metal out.

Another advantage is that the broader the chisel the easier it is to hold its edge fair with the work surface and make smooth chipping. The chisel-point I must make as thin as possible, the thickness shown in my sketches being suitable for new chisels. In grinding the two facets to form the chisel, I must be careful to avoid grinding them rounded as shown at A in the magnified chisel ends in Fig. 4, the proper way to grind them flat as at B in the sketch. I must make the angle of these two facets as acute as I can, because the chisel will then cut easier.

The angle at C, in Fig. 5, is about right for brass, and that at D is about right for steel. The difference is that with hard metal the more acute angle dulls too quickly.

Considering the length of the cutting, it may for heavy chipping be made straight as in Fig. 1, or curved as in Fig. 3, which is the best, because the corners are relieved of duty and are therefore less liable to break. The advantage of the curve is greatest in fine chipping, because, as you see in Fig. 6, a thin chip can be taken without cutting with the corners, and these corners are exposed to the eye in keeping the chisel-edge level with the work surface.

In any case I must not grind it hollow in its length, as in Fig. 7, or as shown exaggerated in Fig. 8, because in that case the corners will dig in and cause the chisel to be beyond my control, and, besides that, there will be a force that, acting on the wedge principle and in the direction of the arrows, will operate to spread the corners and break them off.

I must not grind the facets wider on one side than on the other of the chisel, as in Fig. 9, because in that case the flat of the chisel will form no guide to let me know when the cutting edge is level with the work surface.

Nor must I grind it out of square with the chisel body, as in Fig. 10, because in that case the chisel will be apt to jump sideways at each hammer blow.

(*To be continued.*)

APERTURES OF THE PRINCIPAL TELESCOPES.

IN an article on the progress of telescopes as regards size, the *Revue Scientifique* makes the following remarks, and gives a list of large refracting telescopes, which we have corrected, down to apertures of 15in.

At the end of the 18th century Herschel gave a very great impulse to physical astronomy. His amazing manual dexterity, his activity, his patience, led to the great works which made of him one of the greatest minds that England ever possessed. Guinand and Fraunhofer led to the realisation of large objectives by the progress they instituted in the manufacture of optical glass, while a mechanism of clockwork compelled the glasses and telescopes to follow the diurnal movement of the stars. All modern instruments are mounted in this manner. The tendency is toward enlargement, so that telescopes have reached such a size that some possess mirrors of 1·20 metres in diameter (Paris and Melbourne), with refractors 0·66 metres aperture (Washington), of 0·75 metre, and even one metre in diameter. Is this mania *for enlargement justified?* Arago, when he asked from the Chamber the credit necessary for the construction of an objective of 0·38 metre, believed that, by raising the enlargement of the glasses to 6,000 times, objects upon the moon 20 metres in length or 2 metres in width should be seen, the causeway of a railroad, fortifications, and monuments. The single difficulty in the way of realising this hope lies in the deficient luminosity of the images. It is yet impossible to determine to what extent the increase of the optical power of a lens or of a telescope is more than compensated by the increase of spherical aberration, the difficulty of manipulation, the instability, and deficiency of light. To give a more exact conception of the fineness of details that are attained in a good instrument, we may recall that Schiaparelli, in his observations upon Mars, made at Milan with a lens of Merz, of 0·218 metre aperture—Mars being distant 14 million leagues during the opposition of 1877—could distinguish a round spot 137 kilometres wide. From Mars an island such as Sicily, a lake of the size of Lake Ladoga or Tshad, could have been seen, a zone of 70 kilometres would have been visible, and Jutland, Cuba, or Panama would have been seen. The lens at Washington, of 0·65 metre, would show details but one-third the size, that is 44 to 24 kilometres; upon the moon the lowest dimensions would be 315 metres in size, upon the sun 177 kilometres, upon Venus 36 kilometres, upon Jupiter 555 kilometres. Experience proves that the most useful aperture is from 0·38 metre to 0·40 metre.

The following is a table of instruments of which the greatest diameter is 0·92 metre. The number of lenses whose diameter is greater than 0·245 metre does not exceed 32.

Observatory.	Aperture in centimetres.	Maker.
Lick, in Cal.	91·5	Clark and Son.
Pulkowa	76·0	Clark and Son.
Nice	76·0	Henry Bros.
Paris	73·5	Martin.
Vienna	68·5	Grubb, 1881.
Washington	66·0	Clark, 1873.
McCormick, Chicago	66·0	Clark, 1879.
Newall, Gateshead	63·5	Cook and Son, 1868.
Princeton, N.J.	58·5	Clark, 1881.
Strassburg	48·5	Merz and Mähler, 1879.
Milan	48·5	Merz, 1881.
Dearborn, Chicago	47·0	Clark, 1863.
Van der Zee, Buffalo, N.Y.	46·5	Fitz.
Rochester	40·5	Clark, 1880.
Madison	39·5	Clark, 1879.
Dun Echt	39·5	Grubb, 1875.
Royal Society (Dr. Huggins)	39·5	Grubb.
Pulkowa (smaller)	39·5	Merz and Mähler.
Harvard Coll., Mass.	39 5	Merz and Mähler.

The observatory at Lisbon has a telescope with an aperture of 14·8in., and there is in course of construction (the above are not all quite finished) a telescope of 28in. or 29in. (71-74 centimetres) for Yale College, by Clark and Son.

HOW TIME-TABLES ARE MADE.

ONE of the most laborious things connected with the management of a railroad is the instituting of changes in the time-table governing the running of trains. Instead of its being done with pen and paper, as many suppose, the entire running arrangement of all passenger and freight trains, their crossing of other tracks or passage of other trains, their stops, and lost time are calculated by simple common pins and spools of different coloured threads. Before a time-table or schedule is prepared the time chart is first perfected. To prepare a time-chart a large sheet of drawing-paper is first stretched on a smooth surface and mounted on an easel. The chart is ruled either for two, five, or ten minute time by horizontal and perpendicular cross-lines. The time is marked above the horizontal line, and the distances, or stations and terminals, down the first perpendicular line. For illustration, 12 midnight is the mark on the first horizontal line, and each hour is marked until the 24th, or the following midnight hour, is reached on the last horizontal line. Between the hour-lines the space is divided into minutes and graduated as fine as desired. On a two-minute chart the space between the hours is divided into ten minutes time, and the ten minutes time into two minutes time. The hour-lines are made heavy, and the lesser lines are of a higher shade to distinguish them. The one terminus of the road—Milwaukee, for instance—is marked on the first line beside the first time-mark, 12 midnight. The other stations follow down the perpendicular line until the other terminal is reached. Then all is ready to prepare for the running arrangement, provided the pins and thread are ready. A blue thread means a passenger train, a red thread a freight train, and if the trains of other roads use part of the track they are designated by a different coloured thread. It is calculated that the running time shall be, say, twenty-five miles an hour, and, for the purpose of illustrating, the tracing of one passenger train will answer the purpose of explaining them all. A passenger train leaves Milwaukee at 8 a.m. A pin is placed on the horizontal line at the 8 a.m. time-mark and the end of the blue thread fastened thereto. If the train runs without stopping for 50 miles, the blue thread is stretched over opposite to the station at which the stop is made, and directly under the 10 a.m. time-mark another pin is stuck, and the blue thread wrapped about it to keep it taut. If this is a stop, say of 40 minutes, the blue thread is stretched to the 10.40 a.m. mark on the direct line with the same station, and another pin stuck and the blue thread wrapped. The train starts and its entire course is thus timed and distributed along the road. If the railroad has, say, 40 or 60 passenger and freight trains running daily, the time-chart, when it is completed, looks like a great spider's web stretched out with pins. But little work then remains to transfer the time and stations to the time-table, and the schedule is ready for the printer.—*Milwaukee Sentinel.*

KNEE-BREECHES TROUSERS.

FASHION, notwithstanding its caprices, is subject to the controlling influences of the sense of comfort and that of appearance. We may say that of these the former influence, on the whole, predominates in the dress customs of the male, and the latter in those of the female sex. On this hypothesis one can understand how a desire for warmth, developing with the growth of civilisation, has led our countrymen, or most of them, as well as our Continental neighbours, to abandon various cooler and lighter, and even more wholesome, modes of covering the nether extremities for that of our own day, which is probably as inelegant, and sometimes as inconvenient, as it is protective. We have left behind us the British kilt, the Saxon leg-swathing, thee thigh-breeches, the knee-breeches, and have put on trousers. Ours is the century of long clothes. It may be questioned whether we have gained much by the change. Some, indeed, of our ancestral garments may, by this time, be too long out of date to be recoverable. The kilt and leg-bandage, for example, are separated from us, not only by centuries of disuse, but by differences of sentiment and occupation between our time and theirs, which must render their revival in any general sense well nigh impossible. The Elizabethan costume is in the same position; but the short clothes of the Georgian era still hold an established place among varieties of dress, though not that of the governing type. They seem to form the chosen habit of those whose lives abound in muscular movement. Thus they set the fashion of boyhood in the knickerbocker suit; they commend themselves to athletes, and especially to those of them who run much; farm labourers often wear them; the infantry soldiers of more than one Great Power find them serviceable. Might they not be even more commonly worn in civil life than they are? We think so, and though we cannot here follow all the intricacies of an argument as to whether or not knee-breeches are on the whole more seemly and convenient than trousers, whether the use of the latter should not be conceded to the man of unshapely limbs, and so, forth; still, it seems to us that in certain conditions at all events the elder costume might be adopted with advantage. Speaking broadly, we may say that all callings which entail much physical exertion would profit by the change. In particular, this is true of labour in the open air. In this form of work especially, where there is frequent and prolonged movement of joint and muscle, the weight of surplus clothing soon occasions weariness, and the surroundings are not the most cleanly. The labourer if knee-breeched and gaitered would be disencumbered of as much heavy moleskin or corduroy as would otherwise fall below the knee, a part of his clothing would not then as now flap about the feet for no good purpose but to be soiled by the mire of his work, or in wet and cold weather to lead to illness by chilling or freezing on his legs. Gaiters of some close and not too heavy material might be worn over the stockings. They would be comparatively out of the way of dirt, would maintain warmth, would brace the muscles by equal and moderate pressure (a noteworthy consideration with men who are much on their feet), and if wetted might be easily removed and replaced by another pair. If some such reversion to a prior type were brought about in the dress of workmen, the change, being one of arrangement even more than of quality of clothing, would enhance the comfort, facility, and effect of their exertions without prejudice to their health. It is at least suggestive that many workmen do endeavour by various devices, such as leggings, straw ropes, and the like, to make as little of their trousers below the knee as possible.—*Lancet.*

CAPTAIN EADS estimates that the ship railway across the isthmus of Tehuantepec can be completed in two years for the sum of 25,000,000 dols.

SCIENTIFIC SOCIETIES.

ROYAL METEOROLOGICAL SOCIETY.

THE Annual General Meeting of this Society was held on Wednesday evening, the 16th inst., at 25, Great George-street; Mr. J. K. Laughton, F.R.A.S., President, in the chair.

The Secretary read the Report of the Council, which showed that the past few months mark a very important epoch in the history of the Society. In October the Council received the intimation that Her Majesty had been graciously pleased to grant the Society permission to assume the prefix "Royal." In consequence, the Society has become, and will henceforth be called, the "Royal Meteorological Society." In December, the Fellows made certain alterations in the by-laws by which the annual subscription has been increased. The Report also showed that the Society is doing a great deal of practical work, not only by holding meetings and publishing the papers read at the same, but also by the establishment of a large number of observing stations which are regularly inspected, so that the results obtained from them may be strictly uniform and comparable. The number of Fellows is 549, and of honorary members 19, thus making a total of 568.

The President then delivered his address, in which he referred to the experiments made by Mr. Saxon Snell, Mr. Bertram, and Mr. Hele Shaw, with the object of determining the coefficients of Biram's anemometers; as yet these can scarcely be considered quite satisfactory; for though made with the utmost care, they give results differing from each other by nearly 25 per cent., and from the known truth in opposite directions. The reduction of barometric readings to sea-level is another problem of great interest and importance, the solution of which is far from perfect, and as applied to the converse determination of altitudes has been pronounced by Mr. Gilbert, of the U.S. Geological Survey, to be beset with difficulties "so numerous and so baffling, that there is no reason to hope that they will ever be fully overcome." In many cases too, the reduction, even if correct, implies an accumulation of air in places where no air exists, and isobars so drawn, traversing mighty mountain ranges, such as the Rocky Mountains or the Himalayas, or elevated plateaus, such as those of central or Eastern Asia, convey an impression which may easily lead to serious mistakes. The great achievement of the year is unquestionably the gathering in of the observations taken, by international agreement, at nine Arctic stations, in which, amidst circumstances of more or less discomfort, parties continued through a full period of twelve months. With one station established by the United States, on the shores of Lady Franklin Bay, it has been found impossible to communicate; this was established in the summer of 1881, and no trustworthy news has since been received. Preliminary reports have been published from the English station at Fort Rae, on the northern shores of the Great Slave Lake; from the German station in Cumberland Sound; from the Austrian at Jan Mayen, and from some of the others; but the principal interest attaches not to the observations taken separately, but to the collation and comparison of the whole, which may be expected to lead the way towards problems of the greatest importance to Meteorology. In the present day, one science is so mixed up with a number of others, and so involved in them, that it is impossible to separate them, or to define the exact limits of each. Many of the problems of meteorology belong as much to geography, or at times even to experimental physics, and an address which speaks of the progress of meteorology is, perhaps, apt to appear in some degree discursive. It is that the true student of nature, whilst limiting his detailed work to one particular direction, must consider her kingdom as a grand and comprehensive whole, one and indivisible.

A Negative Thermometer.—The ordinary mercurial thermometer is, as is well-known, based on the dilatation of bodies by the action of heat, and on the difference of dilatation between mercury and glass. A new thermometer in which the mercury column sinks with a rise of temperature, has moreover, been introduced by M. D. Latschinoff, who has based his instrument on the discovery of Kohlrausch that the coefficient of dilatation of ebonite is greater than that of mercury. Latschinoff has made the reservoir of his thermometer of ebonite, and the result is that the level of the mercury falls in it when the temperature rises, and, on the contrary, rises when the temperatue falls. A rise of 20° Cent. lowers the mercury 25 millimetres. The result is curious; but ebonite is so untried a substance for thermometry, that we may be permitted to doubt if it will give accurate and constant indications with lapse of time.—*Engineering*.

SCIENTIFIC NEWS.

FROM *Dun Echt Circular*, No. 83, we learn that Prof. Krüger, of Kiel, has telegraphed a message received from Melbourne, announcing the discovery of a small comet on January 12, in R. A. 22h. 40m. and S. Dec. 40° 8′ moving rapidly south-east. The circular notes that unless some error has been made in transmitting the message from Australia, the comet does not at present seem likely to become visible here.

A curious announcement recently appeared in the *Times* to the effect that Dr. Gould, of Cordoba observatory, had telegraphed to Buenos Ayres on December 15, his discovery of five comets, all small ones! One of the Buenos Ayres newspapers thinks they account for the extraordinarily hot weather experienced in the region of the River Plate, and we suppose also for the equally extraordinary cold weather experienced in Georgia and Louisiana.

The Cunningham Medal of the Royal Irish Academy was awarded to Mr. John Birmingham, of Tuam, at the meeting held last week, when the president, Sir S. Ferguson, F.R.S., gave a brief description of Mr. Birmingham's labours in cataloguing coloured stars. "The Red Stars" was published in the *Transactions* of the Academy in 1876, and Mr. Birmingham is now engaged in revising and supplementing the lists, so as to bring them up to the present time. The Rev. Dr. Haughton characterised Mr. Birmingham's work as a unique and important contribution to science.

In the course of a Gilchrist lecture delivered last week at York by Prof. Ball, on "The Moon and her Volcanoes," the lecturer said that perhaps the most philosophical conclusion was that throughout space there might be life adapted to existing circumstances, as was the case over the face of the earth.

From the *Abstracts of Proceedings* of the Liverpool Astronomical Society we learn that observational work has been divided into seven sections, and that volunteers are coming forward to assist in the practical work. The latest instalment contains a paper by J. E. Gore, F.R.A.S., on "Chi Cygni," with a lithographic chart of the vicinity. The Rev. T. E. Espin also gives an account of observations made during the late maximum of that variable, while Mr. Sawyer, of Cambridgeport, Mass., contributes a note on the "Variable R Leporis." Amateurs who are desirous of doing real work with the telescope, cannot do better than become members of the Liverpool Astronomical Society, or, at least, join in the labour of one of its sections.

Prof. Flower has accepted the post of superintendent of the Natural History department at South Kensington, vacant by the retirement of Prof. (or Sir R.) Owen, and the Royal College of Surgeons will consequently have to elect a conservator of their museum.

Mr. Clement L. Wragge arrived in South Australia on Dec. 6. He has made a number of meteorological observations, and when passing through the Suez Canal he collected a large quantity of marine shells. While crossing the Australian Bight a thunderstorm occurred, and the self-recording barometers showed that there were two distinct storm centres.

It is stated that nearly sixty lamps have been sent in to compete for the prize of £500 offered by Mr. Ellis Lever for the best safety lamp. They come from various parts of the Continent, America, and the United Kingdom. The apparatus erected at Woolwich by the Royal Commission on Accidents in Mines will be placed at the service of the adjudicators as soon as the experiments conducted by the Commission are over; but it will necessarily be some time before the award, if any, can be made.

A remarkable "recovery" is reported from the neighbourhood of Whitstable in the person of a woman, who for twenty years had lain in a helpless condition and had become "quite black." Her brother was recently sentenced to imprisonment, and on hearing of the sentence the woman suddenly regained her normal complexion.

At a meeting held at the Parkes Museum last week, Mr. T. P. Teale, of Leeds, delivered an address on the economy of coal. Instead of a solid bottom of fireclay or iron, Mr. Teale incloses the ashpit in such a manner that little air can reach the fire beneath the grate. By this means, it seems, the coal is reduced to a fine ash, which falls through the grate, and the poker is not required. The stove is all the better if the back and sides are made of thick fireclay, or if an arch of fireclay be arranged to interrupt part of the ascending heat.

In our *résumé* of "The Progress of Astronomy in 1883," on p. 375, we remarked, apropos of Dr. Huggins's supposed photographs of the Solar Corona, obtained from the uneclipsed sun: "It is now suspected that the pseudo-coronal structure visible in his negatives may have its origin in reflection from the dark backing of his photographic plates, such backing being painted on with a brush." In connection with this paragraph we have received a letter from Dr. Huggins himself, couched in terms so strong that we are persuaded that he would modify them on reflection. In no existing scientific periodical has more ungrudging testimony been rendered, or more ample justice done, to the imperishable work of Dr. Huggins in Celestial Physics, than in the ENGLISH MECHANIC. The very words in which his name is introduced, in the paragraph to which he takes exception, as that of "our greatest living English spectroscopist," might surely have convinced any reasonable man of our earnest desire neither to underrate him nor his work. We have not, ourselves, seen any of his photographs, but founded what we wrote on information derived from a gentleman who had himself examined some of Dr. Huggins's earlier negatives; which —in his opinion—showed indubitable traces of reflection from the backing of the plate. That we were mistaken in our supposition that such reflection arose from *brush*-marks, however, is evident from the fact that we have Dr. Huggins's own assurance that the varnish was spread with a flat wooden spatula. That the main rift in the Corona, visible on a plate taken during the total Solar Eclipse, is also seen in three of Dr. Huggins's negatives, affords, *pro tanto*, proof of the objective reality of his photographs: but until such reality is demonstrated, we venture to think that the origin of the seeming coronal structure on his plates "may" be "suspected," without justifying the strong language which Dr. Huggins has thought fit to address to us.

The "cold wave" in America seems to extend over a very wide area, and for certain parts the temperatures recorded are unprecedented. In the first week of January, the following temperatures were reported:—48° below zero at Jamestown, Dakota; 27° below zero at Chicago; and 20° below zero at Louisville, Kentucky. The temperature at Mobile on Jan. 6 was as low as 20° above zero, and the whole crop of spring cabbages is believed to have been lost. The last statement serves to indicate that no mistake has been made about "zero." At Charleston, S. Carolina, which is in about latitude 30°, the thermometer on the morning of Jan. 6 registered 13° above zero, the coldest weather known there for 135 years. In some of the Northern States the temperature has been reported as more than 40° below zero; but no particulars of the thermometers used are at present forthcoming.

In moving the adoption of the annual report, the Chairman of the Metropolitan Railway said that during the past ten years the company had carried 600 millions of passengers without an accident more serious than a fall on the platform or a pinched finger. During those ten years 3,000 deaths had been caused by carriage accidents in the streets of London.

THE Bill promoted by the Channel Tunnel Railway Company will not be presented for Parliamentary sanction next session. The South-Eastern Railway (Channel Tunnel) Bill is to be proceeded with.

A MECHANICAL absurdity recently announced is a steam-engine with two curved cylinders. This, of course, requires curved pistons and rods, which are connected to cross heads that are required to transmit the power on a straight vertical plane. The obstacles to this are overcome by a complicated mechanism having some relation to a parallel motion. If the intention of the inventor was to see how complicated he could make a simple machine, he has been tolerably successful: but if it was to make a steam-engine for practical use, it is difficult to see that he could have more effectually contrived how not to do it. This engine will probably be described as of "simple design."—*American Machinist*.

Sunday and Monday evenings, January 20 and 21. On Sunday it was observed at 5.30, notwithstanding the prevalence of a ruddy sunset afterglow; and on Monday evening it was observed amidst the gaslights of the city from 6.30 till 7 o'clock.

I have just been conversing with a gentleman who distinctly remembers this comet in 1812.

T. P. Barkas.

BLUE MOONS.

[22269.]—While observing a planet (supposed to be Venus or Mercury, or some of that lot) during one of the late rosy sunsets, it struck me that the recently described blue moon was a gigantic natural fraud, and at the best but a poor imitation of that beautiful and original artificial phenomenon first discovered by a well-known soapmaker, and so prominently brought before the public by means of his advertisement.

A. C. M.

"ASTRONOMICAL NOTES."

[22270.]—In consideration of the number of subscribers that you have in the United States, Canada, and, doubtless, other distant parts of the world, would it not be possible for you to insert the "Astronomical Notes" for each month in an earlier issue of the paper than at the present time. Thus your subscribers here would have the benefit of a whole month's Notes, instead of a little more than half a month as at present. "Astronomical Notes" for December appeared in the issue of Nov. 30th, and I have not yet received, nor do I yet expect those for January. Can you provide for your distant subscribers, who esteem your paper so highly? If so, you would gladden our hearts.

Chas. Bowden.

526, North Second-street, Camden,
New Jersey, U.S.A., Jan. 4.

[We fear we cannot. With our world-wide circulation, our "Astronomical Notes" must necessarily be only locally of use. If we consulted the convenience of our American readers—and nothing would give us greater pleasure were it possible—why not those in New Zealand and China, in Nova Zembla and the Falkland Islands? To do that, we should have to devote several pages a week to "Astronomical Notes."—Ed.]

MICROSCOPIC MOUNTING.—VII.

Staining.

[22271.]—I. *Staining in General.—Transient Stains.*—The use of microscopic staining (which is only dyeing on a small scale) is, as distinguished from its mere prettiness, to render objects more distinct and help us in discriminating one tissue from another by their being affected in different ways. It is consequently advantageous not only to employ permanent stains for mounting, but also to apply quickly-acting though transient staining fluids in fresh examination. The transient stains are, briefly: iodine, magenta, sulphuric acid, sulphuric acid and syrup (Schultze's test, and Pettenkofer's test for bile), nitric acid, and acid nitrate of mercury (Millon's test: colours nitrogenous, or, in other words, albuminoid matters, red). Fresh examination ought never, of course, to be neglected; just as whatever is examined with the microscope ought, if large enough, to be previously examined closely with the naked eye, and torn, cut, &c., in various directions to see what its make is. Fresh examination is requisite, if only to show what there is in the object to be brought out by appropriate processes of mounting, and a very much more real and practical acquaintance with objects may be gained by fresh examination and mounting combined, than can be expected to be acquired by mere inspection of mounted specimens. Here, however, we have to do with mounting, and consequently with permanent stains. These are (1) metallic impregnations; (2) carmine and hæmatoxylin; and (3), the aniline and phthalein dyes, in going through the first of which we can include the necessary explanations on the *rationale* of staining.

II. *Metallic Impregnations: Diffuse, Bioplasmic, and Special Tissue Stains.*—Stains appear to act in three ways—firstly, they get in, and colour because they cannot get out—quite independently of any special affinity they may or may not have for the tissue acted on, and simply on account of something having been done which fixes them within it. For this reason, tubes, &c., are often highly coloured; and aniline dyes penetrate into the xylein and bast portions of vegetable sections, and into the interior of thick-walled epidermic cells—wherever there is a thick cell wall, in fact—and have not time to escape through subsequent rinsing with spirit before they are arrested by oil of cloves or some other medium. Magenta, however, like carmine, is a bioplasmic stain. So, again, by penetrating a tissue with a dilute solution of sulphate of iron (green copperas); and following this up, after imperfectly washing the object, by a dilute solution of pyrogallic acid, an exceedingly fine precipitate of what is, in reality, black ink, will be produced within it (*Dr. Frances Hoggan's method*), giving a neutral tint, which produces distinctness, or may serve as a background for other stains. *Prussian blue* may also be formed in the interior of the object by penetrating it with a dilute solution of yellow prussiate of potash, and after imperfect washing, following this up by a dilute solution of perchloride of iron; but wherever prussian blue is used, the object must not afterwards be exposed to alkalis. In these cases it is plain that the stain is formed simply because the fixing agent penetrates before the agent which it fixes has escaped: and any difference of staining must be due to difficulties of escape caused by thickness of cell-walls, tubular or other recesses, thick or syrupy cell contents, or crannies, joinings, or irregularities of surface, by which the stain is detained. This merely physical or mechanical factor is more or less operative in all staining; and the *rationale* of many apparent irregularities will be apparent if it is borne in mind. *Molybdate of ammonia* also gives a neutral-tinted background. *Nitrate of silver* has but little power of penetrating tissues; but it has a special liking for the slight irregularity produced by the junction of surface cells, which it is therefore used to render conspicuous. A 10 per cent. solution (a drachm to an ounce and two drachms *of distilled water*) may be made when required, and diluted as necessary (with 4 to 40 parts of distilled water). The object darkens on exposure to light (better with a little salt), and the solution must be kept in perfect darkness, the bottle being covered with blackened paper, with black varnish, or both.

Another way in which stains act is through the albuminous matter in the tissues, operating as a more or less feeble mordant, or, as a substance which absorbs the dye more than the others, and is inclined to retain it when the others give it up. This happens more or less with most stains, and especially with perchloride of gold, osmic acid, carmine, and hæmatoxylin; it is probably partly physical, due to the gluey nature of the albumen. White of egg is nearly pure albumen and water; but as albumen is also used as a mordant in dyeing, it is also, at least in many instances, partly chemical: and it is of great importance in microscopical staining, for albumen is one of a closely-related group of very complex, readily alterable, and easily coagulable substances—blood albumen, egg-albumen, vegetable albumen, fibrin, casein (the coagulable principle in milk), &c.—from which the other bodies formed in animals and plants are constructed. The albuminoids exist diffused through the juices as the albumen in the fluid, as distinguished from the corpuscles of the blood; but the celebrated protoplasm or bioplasm is an individualised, semi-solid, moving albuminoid. Hence stains, in so far as they are mordanted by albumen, are specifically bioplasm or protoplasm stains. While, therefore, molybdate of ammonia or ink formed within the object are diffuse stains or non-discriminating general backgrounds, perchloride of gold, osmic acid, &c., are bioplasm stains.

Perchloride or Terchloride of Gold is a yellow salt sold for photographic purposes in glass capsules, each containing fifteen grains, so that if the contents of one of these capsules be dissolved in three ounces of water, a one per cent. solution will be formed, than which nothing stronger will be needed. Gold is used to the best advantage on fresh objects; and though it will often stain those which have been hardened in alcohol, or even in chromic acid, it sometimes refuses in the most determined manner to have anything to do with them. Like other bioplasmic stains, it acts more rapidly and intensely in proportion to the quantity and activity of the bioplasm present (though the question of "could get in and could not get out," has to be considered); stains animal more than vegetable objects; in summer than in winter; and in warm than in cold weather. With leaves and other parts containing chlorophyl it gives a dirty disagreeable tint (hæmatoxylin, also purple, is here better); but may be used for the other parts of plants, and, among animal tissues; stains best mucous tissues, glands, the skin, nerve, muscle, and cartilage *cells*. Its normal colours are blue, various shades of purple, ruby-red, and brick-red, all of which may be seen in the same section. For instance, as anything is stained which throws down the gold, black-blue blurs often indicate in plant-sections the position of latex vessels or other cavities containing special products. It frequently abstains from staining the nuclei, which may then appear green by contrast; and, even in very dilute solutions (·003 — ·006 p.c.), exercises a hardening effect on the protoplasm, without, apparently, contracting or otherwise changing it. But, *as with other stains*, the effects of the other reagents which may be employed along with it have to be taken into account.

To stain with gold, the objects, after having been washed clean from any adhering matter, may be immersed in a very weak dilution of acetic acid (·05 — ·5 p.c) till it has penetrated throughout, which it will do in an hour or less according to their bulk and density. They are then to be put into a gold solution (·02 — ·5 p.c.), and left there till they assume a yellowness distinct from that of the solution in which they lie (ten minutes to two hours). On removal from this they must be thoroughly well washed, so as to remove all superfluous gold; after which they may be immersed in concentrated solution of tartaric acid or acetic acid, 1 per cent. or so, or hydrochloric rather weaker; and exposed to as bright daylight as possible, to develop the permanent colour. Solution of sulphate of iron has been also recommended, but I think hydrochloric acid is chiefly used, and the iron has in my hands given rise to a disagreeable smoky tint. The permanent colour appears in a few hours, at first, perhaps, in patches; it often darkens with each change of fluids, and if not allowed to develop itself fully before mounting, does so afterwards, so that some of the sections or other objects may finally become so deeply stained as to render them useless. To guard against this, expose the objects to light from the first application of the gold up to the final mounting, which may easily be done by placing them in a mounting pot, or a watchglass with a glass circle over it; do not hurry the mounting; cut the sections as thin as possible, so that there may be less thickness for the gold to stain; and, as directed above, wash the residual gold solution thoroughly well out. Another plan is to leave the objects in the gold solution till the final colour has fairly developed itself, and then wash; but this may give rise to a speckled or dirty look, arising from irregular precipitation. This look may also be due to the use of too strong solutions, and the addition of glycerine to the liquids tends to prevent it. Their action is slowed by the glycerine, but this may be corrected by the addition of a little spirit. A third way is to render the objects slightly alkaline by steeping in diluted *liquor potassæ*, then just to immerse them in water with a little acetic acid to correct surface alkalinity (which might cause a cake of gold precipitate to form on their surface), and then to let them lie in a gold solution. The gold then gets in and cannot get out, being precipitated by the potash, or a deeply staining double chloride of gold and potassium may be formed. Insect structures cleaned by *liquor potassæ*, as the pad on the foot of a fly, may be thus stained; but the method first given is the orthodox one.

Osmic Acid, which is usually obtained in a 1 p.c. aqueous solution sold at the very high price of a shilling a drachm (with a reduction on taking a quantity), is volatile, and must be covered while acting, has a strong smell somewhat resembling that of chlorine, and very irritating to the eyes and nostrils, and stains yellow or grey, passing into black. It is much easier to manage than gold, because though with it also the colour intensifies (especially if it is not well washed out after staining), the final colour is merely an intensification of the first. It stains very much like gold, except that it blackens fats and tissues which, like nervous tissue, contain a considerable amount of fatty matter, and also resembles gold in the circumstance that dilutions of very different strengths have to be used on different occasions. The fainter stains are better than the very deep ones, which are apt to be blotchy, mottled, or granular, so that as weak a dilution as will stain should be employed; and sometimes only a drop or two of the 1 p.c. solution to a couple of drachms of water will be sufficient. As in other cases, the addition of glycerine moderates the action, and tends to prevent the specks or blotches. Osmic acid is also a killing, a hardening, and a preserving agent, and, as it thus kills four birds with one stone, has been much used on very minute and very delicate objects which will not bear much handling or many transfers of fluid—such as embryos, minute polyps, and specially alterable components of higher organisms. Staining minute objects also renders them more visible. It is advisable not to mount the preparations at random in glycerine, as the colour then sometimes vanishes altogether or in patches. Small water worms, stems to which vorticellæ or bell animalcules are attached, &c., may be placed with a little water in the cell in which they are to be mounted; to kill them, the 1 p. c. solution may be gently applied by means of a small tube, and the objects washed with water as they blacken. They may thus be seen sometimes with their cilia extended; the cilia on the gills of a fresh-water mussel become very apparent. On the other hand, the animal may have time to withdraw its cilia, tentacles, &c., before dying. Whether it will do this or not will depend partly, perhaps, on its being hungry, and partly on the thinness and permeability of its integument and the rapidity with which a sufficiently strong solution of the acid is brought into contact with it, without contraction being previously induced by (e.g.) the plop or shock of a *drop* of osmic acid against the water. Apply, therefore, in a continuous current from the tube. Like osmic acid, *Picric acid* also kills, hardens, preserves, and stains (the stain being yellow), so that it may be here noticed, though not a metallic impregnation, nor a dis-the train in question. And here I think we may get a practical use of the h.p. of an engine, for by its aid we can calculate the rate at which an engine will take a train up a known gradient.

The horse-power used against train resistance is given by the expression

$$\frac{120284\ Wv + 88\ Wv^3}{3762000}$$

using Mr. Luis' formula. The total work done in going up a gradient of 1 in m. is given above, and we therefore have the equation

$$\frac{120284\ Wv + 88\ Wv^3}{3762000} + \frac{197120\ Wv}{33000m.} = P.$$

where P is h.-p. From this we get $3{,}969{,}372{,}000\ Wvm + 2{,}904{,}000\ Wv^3m + 741{,}568{,}440{,}000\ Wv = 124{,}146{,}000{,}000\ mP$, in which v is supposed to be the unknown quantity. This equation is a cubic with its second term missing, and may be solved, after putting in the known values of W, m, and P, and suitable reduction, by Horner's method of continual approximation. It must have at least one real root, although the other two may be imaginary. I cannot agree with Mr. Gobert that the h.-p. is (necessarily) very variable during a journey, and think I have pointed out the fallacy upon which the statement is based—i.e., neglecting the work done in ascending inclines. I will esteem it a favour if he will send Hrabak's formula, to which he makes reference, and shall be glad to learn his views—versus "Historian"—as to locomotive designing.

Elswick Science School. **Wm. John Grey.**

[22277.]—THE latter part of Mr. Gobert's letter (22254, p. 429) furnishes so completely the information for which Mr. Grey asks, that it seems perfectly unnecessary for me to take up valuable space by simply giving similar facts.

There is no doubt that work done can be expressed in terms of horse-power by multiplying the total resistance in pounds by the velocity in miles per hour, and by the constant number 2·66, cutting off five figures from the right-hand of the product for decimals; the remainder is the effect in terms of "horse-power."

As I have before said, the power of locomotives is not calculated by horse-power on account of the "uncertainty." I agree with Mr. Grey, that "knowledge is amply worth having,"—that is, if it be useful and practical; but it appears to me that to obtain formula about which "uncertainty" exists, and, as Mr. Gobert truly says, "cannot be depended upon," is a kind of knowledge which may do great harm by misleading the young engineering student; therefore, I hope the expression "horse-power of locomotive" will henceforth find no place in the columns of the ENGLISH MECHANIC.

Mr. Gobert, in my opinion, does not calculate the resistance high enough for practical everyday working: the formula $R = 8 + \frac{v^2}{171}$ was given in your XXIXth Volume, p. 92, and is all very well for experimental trains in good order. Mr. D. K. Clark, in his "Locomotive Engineering," p. 290, states that resistances calculated by this formula "should be increased 50 per cent., or one-half more."

Now, in looking over Mr. Gobert's formula, I do not see that he increases his results by 50 per cent., as Mr. Clark in his book tells us must be done for daily working, and he uses formula $R = 12 + \frac{v^2}{114}$, which I find very correct.

Experiments were made at Newark to determine the resistance of trains, and I should be glad to know the highest and lowest constant resistance per ton then obtained, in order to compare it with recent experiments.

In conclusion, it may interest your readers to know that on the Manchester and Derby line (which has many curves) trains made up of bogie carriages and cars are running with *two pounds per ton less resistance* than trains of the same weight and same speed, when made up of four or six-wheeled coaches. This fact is one of importance, and appears to confirm an opinion which Mr. Stretton expressed in your columns of April 4th, 1879. With the present heavy express traffic, it is, above all, necessary to reduce the resistance per ton.

Historian, M.I.M.E.

COMPOUND ENGINES.

[22278.]—FROM the number of letters that have appeared in your valuable paper on the above subject, there appears to be much interest taken in, and a great diversity of opinion with regard to, the benefits derived from compound engines in comparison with the single-cylinder engine. I should take it as a great favour if "Engineer, Dewsbury," would kindly show what amount of power he would derive from his compound engine with the receiver placed between the two cylinders, and working with the cut-off as laid down in his first formula? Also, what would be the capacity of the receiver he would use.

Bradford, Jan. 19. **Young Engineer.**

[22279.]—IN reply to "Engineer, Dewsbury" (letter 22253), I did not misunderstand my informant respecting the lead of the pistons. I have many times seen them as stated by "Engineer," the low-pressure leading, notably in the compound engines made by Messrs. Galloway and Sons, Manchester. But the party I mentioned expressly states that the high-pressure was leader, and by only a few inches, and some diagrams I have seen appear to bear out the statement.

Its being out of common practice was my reason for asking an opinion upon it.

Celeriter et Fortiter.

THE MANUFACTURE OF ALUMINIUM.

[22280.]—MR. GREY'S figures (22264) are no doubt correct; but it would have been as well had he taken the advice he quotes, and not rashly declare a thing impossible because he cannot accomplish it himself. Facts speak for themselves. A salt of aluminium has, and can be, reduced by sugar. This is carbon in a peculiar form and combination, and it is very probable that no other form of carbon, except a multiple of the formulæ ($C_{12}H_{22}O_{11}$), would have the like effect.

A. E. S.

A HAND-WARMER FOR PIANISTS.

[22281.]—WITH reference to the letter (22210) of your esteemed correspondent, Mr. W. H. Davies, I perfectly recognise the value of the warning he gives, but am happy to say that the little apparatus mentioned in my former letter (22247) is not in any way open to the objection mentioned, it being adjusted *outside* the piano, immediately in front of the keyboard. I have now used the hand-warmer for two winters, and do not find it at all in the way of the knees, as it comes some little distance above them. It is a true, if not an elegant, saying, that "the proof of the pudding is in the eating," and I may remark, generally, that I have found this apparatus most satisfactory in every way, and I certainly do not see the slightest drawback in it. At the same time, I should be very pleased indeed, as would also, no doubt, a very large number of your other readers, to know whether any other hand-warmer has been seen, or used, or heard of, by any of your musical correspondents. With regard to the suggestion of Mr. Davies, that the best plan of warming the hands is to give them a good exercising for five minutes with scale practice, I can only trust that Mr. D.'s experience in this matter has been less bitter than my own, for I have the most vivid recollections of many and many a time, when my hands and fingers have been so thoroughly numbed and cramped with the cold, that scale practice, or any other practice, was simply impossible.

W. Ritchie.

OIL GASWORKS — COILS AND PARAFFIN PAPER—PARAFFIN LAMPS AND BURNERS—ELECTRIC BELL—FISH-GLUE — WATER-CISTERNS — MURAL DECORATION — RE-COVERING SILVER—TONING PRINTS.

[22282.]—Do I understand Mr. James Copcutt (22263) to say that the gas made from oil by his retort can be preserved in a gasholder? and can he say how much gas will be made from a gallon of petroleum oil? Will it keep without condensing as well as ordinary coal gas? As there can be no question about its being better than coal gas, even if we don't think of anything but the sulphur. Mr. C. offers more information. I certainly should like to have it, as the apparatus could be fixed at the back of the kitchen fire, and the gasholder in the coal vault. Is there any danger of the back pressure forcing the oil out of the tube and funnel?

I did not answer Mr. B. Harcourt's reply to my letter on coils, as I have never tried the method he suggested: but it seemed to me like putting two coils together, joining the cores by an iron cross-piece at the back, and using one contact breaker. He will never be troubled with his paraffined paper cracking if he makes it according to my method. Use fine white tissue paper, not the straw-made stuff that drapers use. If it cracks, there is too much paraffin.

My oilman tells me that the burners of paraffin lamps will not burn properly when they get old, but he cannot tell why. Perhaps some correspondent may be able to say why this is. It is not to save the few pence for a new one, but I am rather curious to know why a burner, with seemingly nothing the matter with it, should cease to give a good light. The same oil burns in another lamp, but this one goes down to nothing shortly after it is lighted; it is not the wick nor the oil which is in fault. While on this subject I should also be glad to be informed how much positive advantage a five-wick burner has over a burner with one wick (for lantern purposes), supposing the one wick to be as broad as the combined wicks placed side by side? The one wick presents a larger surface both to the condenser and to reflector, as there are no interspaces, which must be between the five wicks. I can imagine two wicks placed at an angle giving a little more illuminating surface. I don't think table lamps, with two 1in. wicks, give as much light as one 2in. wick would do. The illuminating portion of a flame seems to me to be very opaque, and I don't think the light from one goes through the other. Mr. Fletcher will, I hope, throw a little light on the subject.

"Chemicus" (52739) will find the bell he wants rather a complicated affair; as, if he wants it to ring a certain time and then leave off, he must have something in the shape of clockwork, which is wound up by the opening of the door—that is, if he requires it to be perfectly automatic; but if any one has to attend when the door is opened, the affair could be arranged with a minimum of personal trouble. The door could be made to turn a lever completely over, and thus make contact. This would have to be turned back by some mechanical action, controlled by a wire, and actuated by the attendant as he entered the room or shop; or a peculiar form of relay could be used, to be stopped by hand. But if the bell is to stop itself, something must be used which will require to be wound up. Any of these methods would be easy to a practical mechanic, as a clock can be easily made to run a certain time and then stop till restarted. The essential parts would be a spring, some kind of governor, a wheel with an arm to lift off the lever, and break contact, also a stop to be reversed by the opening door. Leclanché battery is the best. Porous cells are about 6d. each, and trying to do without one will cost more in the end, and you can't get a really good form of battery without them, or they would not be used. A bladder can be substituted.

If the American fish-glue (52697) is such "wonderful stuff," why does not "Architectus" send the recipe to the "E. M.," instead of asking the correspondent to advertise his address? It is the very thing we want—"costs nothing and is invaluable."

The cause of trouble in "Engineer's" water-cistern consists in the fact that if it is a new one it has not been completely coated with zinc, and the iron rusts through the spots. In this case, coating of zinc is a positive injury (but a negative element), as it sets up a galvanic action; the oxide of iron is forced through the hole in the zinc, and spreads itself out on the surface, and, of course, comes off with the least motion of the water. If the cistern is an old one the cause is the same, as the coating of zinc, however perfect it may be, is thin, and won't last for ever. The remedy, as Mr. P. Ward says in one of his replies, "is obvious."

I am delighted to see ladies reading the "E. M.," and still more so to see them writing for information; but it is only another proof (if one were needed) of the increasing value of our wonderful journal. I am sorry I don't know much about mural decoration (52623), but I think distemper colour is mixed with water. What "E. C. N." wants is called "flatting." The colour is mixed with turpentine, and it has just sufficient boiled linseed oil added to it to prevent it from being rubbed off, and not enough to give it that glossy appearance which paint generally has; if properly done it can be washed *ad lib.* The walls must be smoothed with pumice, and each coat of paint the same except the last, and the paint itself should be strained through coarse muslin.

To recover silver (52751) from iron which has been plated, I should file off the silver, preserve the filings and dissolve off the iron with dilute sulphuric acid. If the iron has not been coppered, the silver will be pure after being well washed. If there is copper it must now be dissolved in nitric acid, and clean pieces of copper placed in the solution; the silver will be reduced on the copper, and may be shaken off into water, washed, and dried. It is as well to neutralise the acid solution with soda or ammonia, stirring well after each addition, and add no more on the appearance of a precipitate. If this is not done, the uncombined acid will dissolve more copper.

52794 has no business to get any red colour with his prints at all. He evidently tries to tone them, after fixing. Take the prints from the frame, wash them, tone them, and then fix; there will be no red colour to get out. Toning bath—sodio-chloride of gold, 2gr.; carbonate, acetate, or phosphate of soda, 30gr. This will tone a sheet of paper. Use warm.

Os.

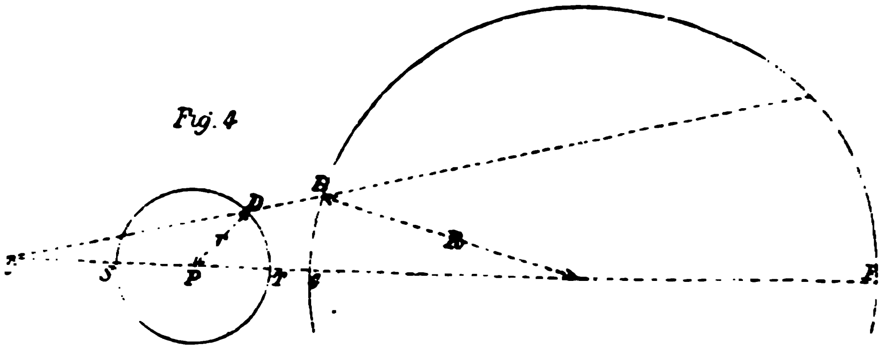
LINKAGES.

[22283.]—IN the following notes I have attempted to explain systematically, and by elementary methods, the simplest ideas of the most important theory of linkages. I must acknowledge my great obligations to Kempe's "How to Draw a Straight Line."

1. Let ABCD be a rhombus which has its side

[illegible]

Fig. 4



line, in the same sense as a pair of compasses gives a mathematically exact method of drawing a circle. It has already been adopted in machinery to replace such devices as Watt's parallel motion, which are used to make a certain point in a machine—e.g., the end of a piston rod—move backwards and forwards in an approximately straight line.

[illegible] If the centre of inversion (O) be not on the circumference of the circle described by the point D then it may be proved that the point B will describe a circle instead of a straight line. Taking this result for granted, we may find the size of this circle, as in the following section.

[illegible] To find the radius (R) of the circle, which is the inverse of a given circle, radius = r, for different positions of the centre of inversion (O).

Let the points F G correspond to the points S T. And [illegible] OS . OF = OT . OG = k.

$$OF = \frac{k}{OS} \text{ and } OG = \frac{k}{OT}$$

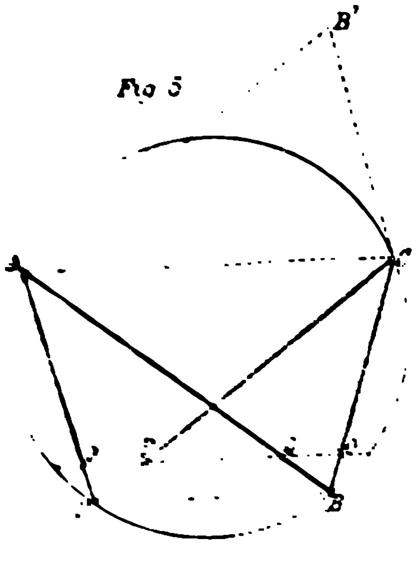
$$2R = FG = OF - OG = \frac{k}{OS} - \frac{k}{OT} =$$

$$\frac{k(OT - OS)}{OS . OT} = \frac{k . 2r}{OS . OT}$$

$$R = \frac{k r}{OS . OT} = \frac{k r}{(OP + r)(OP - r)}$$

Now from [illegible] we see that k = $OA^2 - AD^2$, and is therefore determined by the dimensions of the cell.

Fig. 5



[illegible] link FD. Therefore [illegible] OP we can make the [illegible] any required size, and [illegible] the greater will [illegible] gives a useful practical [illegible] of very large [illegible] curves, such as are re[illegible] engineers' and [illegible] seen that only a [illegible] of the circle F G [illegible]

[illegible] four links [illegible] figure at A. [illegible] C B, they will [illegible] be turned [illegible] then we shall [illegible] hence the [illegible]

[illegible] have their sides [illegible] therefore, equal in [illegible] A C is parallel [illegible] however the [illegible] = [illegible] D C B, therefore a circle may be described so as to pass through the four points A, B, C, D.

12. To prove that, if the four points O, P, Q, O¹ be taken, dividing the links D A, D C, B A, B C proportionately, O, P, Q, O¹ will remain in a straight line.

For ∵ D O : O A = D P : P C, ∴ O P is parallel to A C (Euc. VI. 2). Similarly O Q is parallel to B D, which is parallel to A C. Therefore O P and O Q coincide, i.e., O, P, Q are in the same straight line. Similarly P, Q, O¹ are in the same straight line. Therefore all the four points O, P, Q, O¹ are in the same straight line, which remains parallel to both A C and B D.

13. To prove that rect. A C . D B = constant.—∵ A C B D is a quadrilateral inscribed in a circle. ∴ rect. A B . C D = rect. A C . D B + rect. A D . C B (Euc. VI. D). But A B, C D, A D, C B are all constant, being links. ∴ rect. A C . D B = const.

14. To prove that rect. O P . O Q = constant.—By similar Δˢ, O P : A C = O D : A D, and O Q : D B = O A : A D. Therefore O P . O Q : A C . D B = O D . O A : A D². ∴ rect. O P . O Q = (A C . D B) × (O D . O A) ÷ A D². But A C . D B = const. by § 13, and O D, O A, A D are all constant: ∴ rect. O P . O Q = const.

15. Hence we see that if the point O be fixed, P, Q will describe curves which are the inverse of one another. This linkage may, therefore, be used in the same way as Peaucellier's cell; and, besides, it is simpler by two links.

Leonard Marshall, M.A.

TELPHERAGE.

[22254.]—In your article on "Electric Railways and Telpherage," of the 14th December, you give to us the credit of having invented the "cross-over parallel" system of telpherage working. *This simple* and inexpensive method is the *invention of our co-patentee*, Professor Fleeming Jenkin.

Your article gives very clearly the principles of telpherage; but we should have liked more attention to have been devoted to the "series" system of working, for although this system requires methods of breaking and making contact at the top of each post, yet the insulation of the sections from one another when a train is bridging a post-top, does not need to be nearly as perfect as with the cross-over parallel system; a most important condition when we consider the great pulls to which the post-top is subjected.

Further, the series system enables many trains to be run by the employment of only a small total current, which is a great advantage as regards economy, since the waste of power in heating the conductor depends on the square of the current, and is therefore very large for large currents.

Ayrton and Perry.

CHESS (AN IDEA).

[22255.]—Being very fond of chess, and wishing others to become fond of it, I have often wished chessmen and boards, &c., were cheaper. Therefore, I should like to ask, Why chessmen cannot be made of earthenware or china, or even tough glass, to answer the same purpose (and as well) as the expensive ones now sold? I have never seen any made of the above named substances, and should like to know if there are such made: and if not, why not?

S. S. C.

NEW PATENT RULES.

[22256.]—The new Patents Act requires that the applicant for an invention shall make a solemn declaration, equivalent to an affidavit, that he is the true and first inventor thereof, and that it is not in use by others, thus abolishing the practice of granting patents to those who had invented nothing and for inventions already in use and well known. The Board of Trade, however, have restored the old abuses by permitting those who will not solemnly declare that they are, but will declare that they claim to be, the inventors, to use a new form of declaration that an invention has been communicated from abroad to the applicant, and he claims to be the true and first inventor thereof, and that it is not in use by others within this realm. The applicant, by using this declaration, implies that the invention had no inventor till it was mentioned to him, and that he became the first inventor by reading the account of it. Some defend the use of this declaration by the pretence that the importer of an invention is, in the eye of the law, and so may claim to be, the inventor: but no man is the importer unless he has introduced the knowledge of it into this country where it was, and but for him would have remained, unknown, which the applicant does not allege, is not required to prove, and, in fact, is never true. He is not, therefore, as he claims to be, the true, and still less the first, inventor. Foreigners are, and always have been, wisely allowed to patent their inventions here; but by this new form they may be defrauded by the grant of the patents they have earned to those who have done nothing to deserve them. That a department of Government intrusted with the administration of a law should be permitted to repeal its most important provisions would be a dangerous innovation, and probably Parliament, when the new rules are laid before it, would, on the petition of inventors and others, annul this new form and restore the law. **J. K. Smythies.**

AMATEUR MUSICAL INSTRUMENT MAKING.—V.

[22287.]—Errata in part IV. 1st. column, 13th line from foot, and top line of 2nd column, "neutral segment" should be *ventral segment*.

We now come to the metal work and keys, which are generally made of German silver or nickel silver, which is used in sheet, wire, or tube, and joined together by hard soldering with silver. The first fittings we require are rings for the sockets of mouth-piece and bell; but if the instrument is in 5 parts, we require two additional rings. Sheet metal is usually numbered by the Birmingham wire gauge, and steel wire by Stubbs' wire gauge; but I will try to give sizes likewise in parts of an inch. Half round wire is generally preferred for making rings, and as this is not easily obtained I give the following method. Take a piece of soft steel about 2in. long, 1in. broad, and $\frac{1}{2}$in. thick, and with a small round file cut a semicircular groove across it $\frac{1}{8}$in. deep and $\frac{3}{16}$in. wide at top; the block may then be hardened if desired, although this is not desired. G. S. wire, about No. 6 or 7, B.W.G. = $\frac{3}{16}$in. thick, is then beaten into this groove with a rather heavy hammer, the block being securely fixed (see Fig. 8). The wire, by this treatment, becomes hard, and must be softened by heating red hot and allowing to cool. A mandrel is then taken the size of the position of ring on clarinet, the circumference measured by a strip of paper, and allowing $\frac{1}{4}$in. for a splice joint the wire is cut rather small. The ends are then tapered, the wire bent up to a circle, a small piece of sheet solder inserted, and the joint tied with fine iron wire. A solution of borax is applied over the joint, which is then gently heated till moisture is gone, and then exposed to the blowpipe and made red hot, at which heat the solder flows. It is then allowed to partly cool and plunged in a vessel of acid, made by adding 1 part of vitriol to 4 parts water. This removes the hard borax, which sadly destroys a file; it is then rinsed in water, dried, roughly dressed with a file, put on a wooden chuck in the lathe, turned up and polished or ornamented by mill or chaser. (See Fig. 9.)

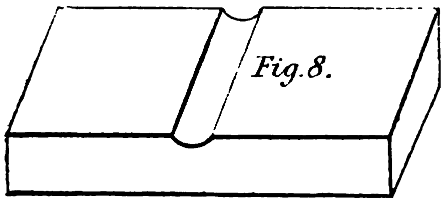

Fig. 8.

Fig. 8A.

Fig. 11.

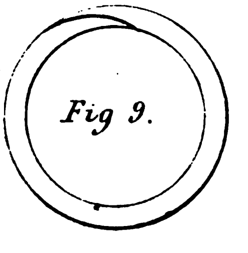

Fig 9.

Rings must be made the exact size, and before putting on are roughened on the inside with a sharp steel point, a drop of thick shellac varnish or glue is put on, and they are then gently driven to their place with a mallet. The following remarks on hard soldering may be useful. Heat always the metal near the parts to be soldered before bringing the joint to its full heat. The solder and also the metal to be joined must be quite bright, clean, and untouched by the fingers; a smoky flame must not be allowed to touch the joint. Fit the metal parts well together, leaving little or no space for the solder, as it runs very thin and will not fill up spaces. Tie the various parts to be joined well together, and if all these points are attended to failure is impossible.

For the borax solution, I shake up ground borax and a small quantity of water in an ounce bottle and apply with a small brush.

Sterling silver is the best solder, as it is not so brittle as silver solder, and this is important, as keys have often to be bent and twisted to suit their places. When two joints are close together both should be soldered at one heat; when this is impossible, the first is soldered with silver and the second with fusible silver solder—fusible solder is 2 parts silver and 1 part brass wire, or 5 parts silver and 1 part zinc. For sheet solder, I take a small silver coin and roll it out as thin as writing paper; it can then be easily cut with ordinary scissors. For wire solder, I buy some silver wire about 22, B.W.G., and draw it down to the sizes required, generally from 22 to 28, softening it by heating and cooling when it becomes hard. A gas blowpipe with foot bellows is usually employed for this work; but for amateurs the spirit blowpipe is cheaper, cleaner, and easier to manage. It may be easily made thus (see Fig. 10):—A is a tin can with flat top and bottom, about 3$\frac{1}{2}$in. diameter and 3$\frac{1}{2}$in. high, air tight, with three openings at the top—viz., B, C, D. B is closed by a cork and is used for filling it half full with methylated finish or spirit; C is closed by a cork, through which passes a brass tube $\frac{3}{16}$in. diameter, on the end of which is an ordinary blowpipe nozzle; D is a brass tube $\frac{3}{16}$in. and 1in. high outside of the vessel, with a long wick going to the bottom of the interior of A, and is used as a small lamp to keep the jet C heated and lighted. E is an ordinary spirit lamp to boil the vessel A. I think the action will be plain without description, the size of jet being regulated by the flame of lamp E. Key shanks are made of flattened wire. This is done by passing round wire of 5, B.W.G. = ·22 of an inch through rollers, or beating it on an anvil to something like the section shown at Fig. 11. Fig. 8A shows section of half-round wire used to make rings. Screws are made of steel, and as they can be bought it does not pay to make; they cost from 6d. to 2s. a dozen. Fig. 12 is a regulating screw with round head, so as not to catch the clothes or scratch the fingers; they are usually about 18 B.W.G. and $\frac{1}{4}$in. long. Fig. 13 is a general watch screw used for fastening flat steel springs, usually $\frac{1}{8}$in. long. Figs. 14, 15, 16, are all special musical inst. screws; 14 is $\frac{1}{4}$in. long: 15 and 16 are about 16 B.W.G., and vary from $\frac{3}{8}$in. to 1$\frac{1}{2}$in. long.

Small G.S tubing is also required for the joints of keys, &c. It may be made by drawing strips of metal through a number of taper holes in a steel plate, the seam being afterwards soldered; but as solid drawn tube is sold in Birmingham it is best to buy, and the size can be reduced by drawing, or widened by boring out. It must fit nicely on screws 15 and 16, and on the steel rods when required. Steel rods.—These I usually get from old umbrella frames, cleaning off the varnish with emery cloth; they are useful for making drills and special screws like Fig. 16, &c. Pillars are required of various sizes, in height from $\frac{3}{16}$in. to $\frac{1}{4}$in., exclusive of screw (see Figs. 21, 22); these can also be bought, so I need not detail their manufacture. Cups for keys are of various sizes, and cannot be bought as far as I know. Fig. 19 is the old shape used 30 years ago; 17, 18, 20, are modern. Those like Fig. 17 we will pass over, as they are difficult to make look neat, requiring great skill and practice to solder in correct position and finish nicely. Fig. 20 is mostly used as a finger key, of which we have one on the clarinet (see Fig. 5, No. 17), covering the back hole; all the rest are like Fig. 19, which has many points in its favour, and holds the pads better than in Fig 17. By referring to table in Part 4, the sizes outside are given for each one required, and as the metal is usually ·5 mill thick the sizes of inside will be 1 mill less. Five sizes in all are required; they are made from sheet G.S., about 22 B.W.G. = ·028in. thick, and are produced by stamping.

WORK DONE BY A MAN IN WALKING.

[22288.]—I am not aware if this subject has ever been noticed in the valuable pages of the "E. M." We are well aware that a man does a certain amount of work in running a mile rapidly, and incurs exhaustion. But what is the actual amount of work performed? and how can we calculate it?

By a little observation we shall notice that a good walker stretches a fair equilateral at each step: taking the length of the legs at 3ft, the body is thrown forward a yard at a time, the right or left leg passing a distance of 6ft. between each lift and fall. Supposing a man to walk with all limbs perfectly rigid, the legs would go through a series of equilaterals of 3ft. base. At each stretch of the legs the distance from their centre to the ground would be 2·6ft.; and as each leg passed the other the body would be at its full height, and the distance from the centre of the legs to the ground 3ft. Hereby a series of rises and falls, each equal to ·4ft., would be incurred, the distance between each fall being 1 yard.

I need hardly say that a graceful pedestrian obviates some part of this rise and fall by such a use of the limbs as causes the impulse to be taken by the muscles, and borne as strain. Still, the actual amount of work is sustained by the body.

Now, a fall equal to ·4ft. per yard is equal to a fall of 704ft. per mile, and a man weighing 140lb. and running a mile in 6 minutes performs 98,560 units of work in the same time as a $\frac{1}{2}$-horse engine would perform 99,000.

A skilful walker sustaining 5 miles per hour for a long day does work equal to a $\frac{1}{4}$-horse engine, and consumes only $\frac{1}{20}$th the weight of food or fuel.

Guernsey Cave.

Pumping by "Suction."—A correspondent recently writing to the *American Machinist* says:—"In all theory, and in my practice, I have been led to believe that it was impossible to raise water by suction over 28ft. or 30ft., and that it was not good practice to pump it over 25ft. But my attention was called to the fact, that at a certain establishment in this city they were pumping water by suction 27ft, and having considerable curiosity, I called to investigate. The engineer stated as a fact that they were pumping water by suction 37ft., that is, from the surface of the water to the suction-valve of the pump, 37ft., with but slight variations. About 25ft. from the bottom end of the suction-pipe is a tee with nipple and elbow. From this elbow, a stand-pipe of the same diameter of the suction-pipe extends to the same height and is covered with a cap. There is a check-valve at the bottom end of the suction-pipe. The explanation is:—Fill both pipes with water, then screw the cap airtight on the top of what I should call the stand-pipe, the action of the pump will suck the water out of the stand-pipe and form a vacuum in it that will sustain the water in the suction-pipe, so that the pump will lift the water the 37ft. without any trouble."

REPLIES TO QUERIES

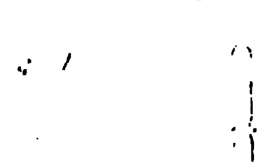
◆◆◆

In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.

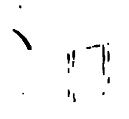
[illegible] **Cancer in the Mouth.**—I beg to [illegible] thanks to the correspondents [illegible] answered the above query. I might [illegible] of my fellow-readers, that the [illegible] "H. O'B.," Vol. XXXVIII., No. [illegible] has done more good to my friend [illegible] remedies he has ever tried.—[illegible]

[illegible]—**Metropolitan Building Act** (U.Q.)—[illegible] that an answer to this query will not [illegible] to "Horloger" now, in consequence [illegible] of time. If all the formalities re-[illegible] of the Act have been carried out, [illegible] owner is, according to Section 92, [illegible] the wie property in the party-wall, till [illegible] share is paid by the adjoining owner, [illegible] obtain an injunction to prevent [illegible] the wall before such share is paid. [illegible] should read carefully the various [illegible] of the Act.—DITTON.

[illegible] — **Soap Cutting and Stamping** [illegible] some slight idea of having read [illegible] the time it was asked; but as I pass [illegible] can only reply from recollection. [illegible] block of soap and decided upon [illegible] slabs it is to be cut into, make a [illegible] nails through a piece of wood about [illegible] thick, let the points of them pro-[illegible] and standing the gauge fairly on [illegible] scribe the soap at each corner: [illegible] means of fine pianoforte wire, a [illegible] which should have two pieces of [illegible] for handles, to afford purchase



[illegible] the soap. To cut slabs into [illegible] The handle is supposed to [illegible] where the dot is, a [illegible] and fastened to [illegible] along the slab it



[illegible] again out into pieces [illegible] and a short wire [illegible] to the air to put

[illegible] an ordinary [illegible] is wanted in [illegible] pieces, [illegible]

[illegible] way to make [illegible] with the [illegible] parts, [illegible]

engine than he imagines. I do not know whether his engine is one of his own make or purchased from an advertised firm. If the latter case, the best thing he can do is to apply to the makers, and see if they cannot help him out of his difficulty. The fault, in my opinion, either lies in the lighting parts or with "Volt" himself not having a correct knowledge of mixing the air and gas supply, which would very likely be set right in a few minutes if an application were made to the maker. If your engine is supposed to fire at every stroke, and does not do so, it is quite plain something is wrong: it should fire when the piston is at half-stroke. My engine fires at every stroke, and works in splendid style. Unfortunately, many of the small motors now offered have many things attached to them that are very troublesome to the purchaser, which obstacles will in a little time be overcome. I have a three man-power gas engine that I have had constantly working for six months (days): it is very simple in construction, with plenty of power. The engine works very steadily, at a cost of about two shillings and ninepence per week for gas—gas at 3s. per 1,000 ft. (This is the outside estimate of cost.) I sometimes work my engine from six o'clock in the morning until nine in the evening without the slightest trouble or inconvenience, so it will be seen I give it plenty to do. During the six months I have had it I have only used one gallon of oil, which is an item of great interest compared with what some engines use. My engine is one of T. B. Barker's, as advertised in this paper, although my intention in writing this is not as an advertisement; neither am I an agent, or in any way connected with that firm. I merely give information that has been asked for, which I am very pleased to be able to do, and shall be equally pleased to show any of "ours" my engine at work if they will call upon—R. STAFFORD, Craven-street, Coventry.

[52389.]—**Sulphuric Acid** (U.Q.)—The rule employed only gives correct results when no alteration in volume occurs on mixing, and this is not the case with H_2SO_4 and H_2O. Thorpe is right.—WM. JOHN GREY, Elswick Science School.

[52430.] **Chemical** (U.Q.)—I do not think this can be done—at least, not by any reasonably practical method.—WM. JOHN GREY, Elswick Science School.

[52451.]—**Peculiarity in Vision.**—This must be due to some action of the muscles of the optical apparatus on the lens, but it would require a very careful examination to determine its exact nature. S. M. P.

[52453.] **C. R. Engines.**—Neither 76 nor 75 can now do the work they could previous to being altered. No. 114 is, perhaps, hardly so bad, but, even at their best, this class was never so good as 76 to 87 lot. As a rule, they do not steam as well as formerly, and the valves are injudiciously set for the class of work they have to do. Besides this, a great source of annoyance are the new injectors and throttle valves: the former do not lift the water properly, and the latter are not to be relied upon. The other engines so altered are 84, 116, and also, I believe, 113. With regard to the size of the cylinders, they run about 17in. I will now say a few words about the "renewals." These engines have been running the limited mails again, but assisted by an eight-footer. 420 class are scarcely ever out of the shops, as they are continually breaking down. It must have struck anyone how unsuited these engines are to the traffic: the 8-footer, with its soft, easy, regular beat, and one belonging to the 420 fraternity coming up behind her emitting a continuous roar. The 420 class, although rebuilt for passenger traffic, are still less suited for fast running than some other classes of 6-foot goods—viz., Nos. 190, 236, 288, and 161 classes, which have never been altered. The fact is, 420 class would give more satisfaction running goods trains. The new inside cylinder goods engines, built by Neilson and Co. (401 to 369), are giving great satisfaction, and I understand that twenty more of the same class have been recently ordered.—SAINT ROLLOX.

[52464.] **Boiler Templates.**—I think full information will be found in Nichols's book, which is sometimes advertised in these pages.—T. M.

[52465.] **Belt Working off Pulley.**—Seeing the difference of opinion that there is on the above subject, I will give a case which I had some time back, which I think will go far towards answering the question and settling the subject. We have a patent indiarubber and cotton belt (layers of rubber and cotton), 10in. broad. This belt is moved on and off the fast and loose pulleys three or four times a day when the engine is at full speed. The consequence is, that the edge of the belt nearest the fast pulley is worn very much more than the other edge, and when it has worn to a certain pitch it begins to travel towards the loose pulley, and do whatever we will we cannot prevent this turning it round regularly. Well, the first travelled towards the loose pulley there was for such was the tendency it had to travel to that side that the belt was thickest, that the friction made the strap-guide almost red hot. It also got against the upper room floor and set it on fire, which gave me and others no little trouble to put out. After this, I took the belt off and turned it round, when it travelled the contrary way: but a few throwings on and off soon got it all right again. I might say that the pulleys are well made, but very near flat. I think the above will prove beyond doubt that a belt will travel towards the tightest side, which is equivalent to travelling towards that part where the shafts are furthest apart or up-hill.—ENGINEER, Dewsbury.

[52477.]—**Sheep's Teeth.**—I think it is only tartar, or a scale caused by the action of acid on the enamel of the teeth.—FARMER.

[52487.]—**Telephone.**—"J. C." will find what he wants in many back numbers. For instance, Nos. 938, 939, 940.—T. M.

[52490.]—**Weight of Pump Valves.**—I think an answer to this query might be found in Mr. Davies's articles on Plumbing.—F. M.

[52491.]—**Legal.**—If you can prove that it was ordered, as you say, deliver it. If it is refused, summon for the value: but be sure that you have proof of the order, which should always be in writing.—LIME O' TH' LAW.

[52504.]—**Legal.**—You, as the leaseholder, must pay. For instance, A. had a house on lease, situated at the side of a country road, the garden being 300ft. long at back. By-and-by the freeholder let the land alongside and at the back, and a new street was made alongside A.'s house leading to a number of houses built at the back. The freeholder charged £5 a year each ground rent, which he put into his pocket, the land having previously been let at £2 an acre. Such, however, is the beautiful simplicity of the law, that while the freeholder made all that heap of money, without either toiling or spinning, the leaseholder A. had to pay for the paving, not only in front of his house, but also for the 300ft. alongside his garden which led to the new houses. He thinks that some reform is needed, though he says he would not mind if he were about to receive any benefit from the paving, which he did not want, or from the new houses erected at the back, which he would rather be without.—LIME O' TH' LAW.

[52518.] — **Water - Wheel.** — My thanks to "Moorman" and "R. J. L." (p. 393). I want the 70 h.p. for a slow steady motion. I cannot well state what it is until my model is complete, when, with the Editor's permission, I will give full particulars. Would a turbine give a *greater* h.p. than a "half-breaster" or "undershot," *the fall of* water being the same?—TINKER.

[52539.]—**Shutter for Photographic Lens.**—I have seen two excellent shutters, one working at the back of the lens, and one in front: the former, with a bellows which opens and shuts by pressing a small indiarubber ball, and allows the operator to give any desired exposure. The latter was shown me by Mr. Wiege, of Berners-street, and is a disc in front of the lens working with a spring and trigger, and will give an exposure as short as the 508th part of a minute. He showed me photos taken with it, two being exceptionally good: a hansom cab turning a sharp corner, and a bird pluming itself: one of the feathers, floating in the air, came out perfectly sharp.—BOSSI.

[52563.]—**Harmonium.**—I think "Fliegen" would do well to consider the reply given by G. Fryer to his previous query, for it is obvious that it is desirable only to convey to the windchest the wind obtained by the feeders. My feeders are each 18in. by 15, and I made ten 1in. holes over each of the wind trunks, and have since made the apertures in the valve-board to the sizes given by G. Fryer. I am unable to answer your query as to the escapement; but if you can obtain a copy of No. 109, Vol. V., I think you will find all the information on that point you can require.—PHONO.

[52563.]—**Harmonium.**—Five holes of 1½in. diameter give a total area of less than 9in., or, for the two wind trunks 17·6in. This is my difficulty. Leaving out the celeste valve, the area of the valves given on p. 248 amounts to 36in., so that when the two rows, 16ft. and 8ft., are being played, there is actually only half the area for the wind to come through from the bellows that there is for it to get to the reeds. I think the dimensions of the valves on p. 248 are too much, considerably. Perhaps Mr. Fryer will kindly say if he ever saw a harmonium with such large valves, and if so, how the escapements were fixed.—FLIEGEN.

[52577.] — **Organette.** — Much obliged to "A. S. L." and Mr. Fryer. Is it not sufficient for the latter that I am acquainted with, I think, all the published lists of music, not only for organettes, but for instruments that were worn out before organettes were born? I want to cut music for myself if possible—original music, and shall be obliged for the information how to set out the perforations. I will wait patiently for the promised instructions.—T. J. P.

[52583.]—**On Demand.**—To "C." — Thanks very much; but I have the notes already signed. I want to know how long they are good security, which I do not gather from your reply.—R. HANNEN.

[52607.] — **Soap.** — It would appear, from "Philo's" description of his plant, than he is in possession of a still without a permit from the Excise. As this involves a penalty, in addition to the costly waste of firing, it will perhaps be as well for him to disregard the statements of those who decry cement--i.e., non-conducting coverings. For the boiler, use one of those advertised in this paper; for the pipes, if under cover, a good lapping of straw bands will be the cheapest; and for the soap-pan, 4½in. brickwork, if it can be arranged. It is possible, however, that in addition to the condensation going on, his boiler, being a small one, primes; and if he cannot avoid this by careful firing, he should have a strong iron box placed near pan, with a steam trap at the bottom; by fitting his steam main to it (the box) he would get rid of both condensed and priming water; but if he is making pale soap only, and not curd mottled, he can open out at the end of the "change in strength" with a bit or two of caustic soda. There is, however, such a remarkable amount of amateur's ignorance (no offence meant) about the queries that have appeared of late *re* soap and its manufacture, that I hardly know how to advise. However, if "Philo" is in the vicinity of a large works he will find a small soapery about as ready a means of dropping money as is at all necessary in this age, when it is not so easily picked up as in the good old times; in truth, I think no business has been so close-run in the matter of profit as the soap trade—not a mere temporary depression, but chronic, without the slightest chance of a turn, and this not only at home, but in the colonies also. So if those who require advice will give some slight indication of the locality their works are in, the county or country (if abroad), I will have pleasure in giving any information I possess. After this long preamble we will return to business. Modern soaperies are fitted up without any exterior-fired pans; and a proper coil or jacket will boil any amount of soap, if proportionate to the size of pan. Inasmuch as the head is boiled out and in of curd mottled by no other means in one of the largest London soaperies, "Philo" may depend upon it that his failure in the use of a coil must arise from small size and weak steam. As for not being able to melt tallow with one, why, surely, he must mean render. Why, even stearine does not require any great heat for its liquefaction; and what chance modern, high-pressure grown, greasy tallow can have against even 5lb. steam I cannot understand. If, however, he really means the rendering down of butcher's fat, his failure is natural enough. Now, if "Philo" will cover his boiler and steam pipes, and use steam at, say, 20lb. pressure, he will not find any need for a dry coil in the making of pale or other close soaps. Of course, his strong leys are not less than 16 per cent. Twaddell cold, if made at his works. If he uses caustic he can go as high as 20 per cent.; but the soap is no better for the excessive graining some boilers give it. How is he going to get strength into soap when it has been curded into peas almost? So long as he gets a fair break in it he can depend upon getting all his excess of strength away, and a much greater amount of dirt and colour in his leys than will come away if he boils his soap hard. The mottling of curd mottle is proof enough of this assertion, as the mottle is only dirt held up by the stiffness of the curd. Have had numerous interruptions during the scribbling of this, and any point overlooked shall have full attention if full details are given with query.—LONDON STONE.

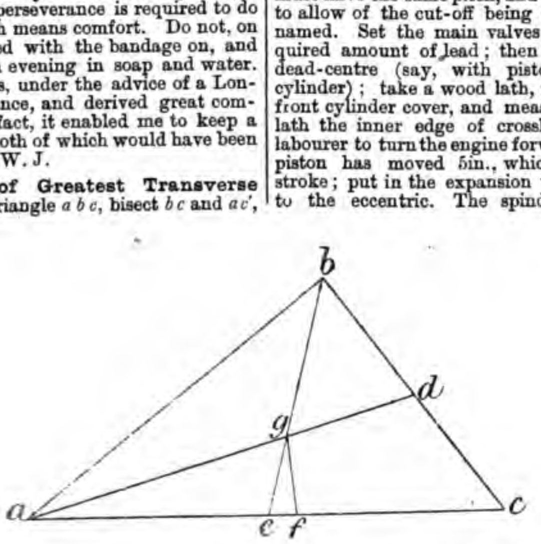
[52620.] — **Pyrotechny.**—"Pyrotechny; or a Familiar System of Recreative Fireworks," by G. W. Mortimer. published by J. S. Hodson, 22, Portugal-street, Lincoln's-Inn; and "The Art of Pyrotechny," price 2s. 6d., published at the *Bazaar* office, 32, Wellington-street, Strand.—R. A. R. BENNETT.

[52632.]—**Gas Fires.**—I have had experience as user of these for some years. Asbestos and pumice stone both smell, besides being, I suspect, unhealthy, as liable to condense noxious gases. Fireclay "fuel" and a single fireclay burner is, I consider, far superior. giving absolutely no smell, besides a far brighter fire. The chimney must, of course, be open.—SATISFIED AT LAST.

[52642.]—**Copper Deposition.**—Iron articles, destined to receive an adherent coat of copper, should be first immersed and soaked in a pickle composed of sulphuric acid and water equal parts, to which has been added of muriatic and nitric acids one-twentieth each of the bulk of sulphuric acid employed. When all rust and dirt have been removed in this pickle, well scour the surface of the iron in sand and water, pick out all sand from holes and crevices with a sharp wire, then rinse well in clean water, and hang at once in an alkaline solution of copper, exposed to the strong current from a dynamo-electric machine until a complete film of copper has been deposited on the article. Then remove it from the alkaline bath to the ordinary electrotyping solution, and put on as thick a coat as may be desired in this solution. Be sure to rinse the articles well whilst transferring them from one solution to another, and lose no time in the process. A useful alkaline solution of copper, to be worked cold, can be made by adding ammonia carbonate, or liquor ammoniæ, to a solution of copper sulphate until the green precipitate, first formed, is all dissolved, and a clear, bright blue liquid appears; then add cyanide of potassium solution to this until all the blue tint disappears, when the solution will have the appearance of old ale. This should stand exposed to the air for a few days to get rid of excess of ammonia before working the solution.—GALVANOPLAST.

[52649.]—**Varicose Vein.**—"H." says, "Much more effectual than ordinary surgical bandage, and much cheaper than ordinary elastic stocking, is Esmarch's bandage, a surgical elastic bandage." Its use is thus described in "Druit's Surgery," p. 774, of the 11th edition:—"It is especially useful in amputations, excisions, and operations on bone. By completely emptying the veins as well as the arteries and capillaries, of blood . . ." If a "Poor Sufferer" asks for, and gets the thing, he won't be troubled with varicose veins very long, nor with a leg either, for that matter. Supposing he uses it, gangrene would set in and the leg rot off. What the correspondent means is a Martin's pure rubber bandage. The best width is about 2½in., and about 3 yards long. They can be had for about 4s. 6d., of any respectable chemist and druggist. There are other makes, perhaps, nearly as good; but a pure rubber bandage is what is wanted. They have been found of immense service in tiresome cases of chronic eczema, as well as for varicose veins. A caution as to their use and mode of application:—Put the bandage on before putting the foot to the ground in the morning. Begin to wind on carefully, holding the rolled-up bandage well in hand, and not letting out more than three or four inches at a time. Let the pressure be just comfortable, and no more. Persuade a surgeon to show how to apply it, if one will kindly do so. In any case, a deal of practice and perseverance is required to do the job neatly; which means comfort. Do not, on any account, go to bed with the bandage on, and wash it carefully each evening in soap and water. I wore one for months, under the advice of a London surgeon of eminence, and derived great comfort from its use; in fact, it enabled me to keep a situation and a leg—both of which would have been *minus* but for it.—R. W. J.

[52654.] — **Point of Greatest Transverse Strain.**—Draw the triangle *a b c*, bisect *b c* and *a c'*, draw the lines *a d* and *b c*, the intersection at *g* is the centre of gravity. Erect perpendicular *g f*, measure the distance $fc = 45 \frac{4\cdot5 \times 10}{10} = 4\cdot5$ tons at *a*, 10 tons 4·5 = 5·5 at *c*, the point of greatest strain.—PALMER, Accrington.



[52653.]—**Electric Current.**—"Antares," p. 435, has not got the matter quite right. He still seems to fancy there is some difference in the currents themselves. This is not so; the difference is due to other elements, and real comprehension requires us to keep each idea distinct. "Density of a current," to which I referred, is not a property of the current, but of the conductor in which it passes. I will give the most striking illustration I know of. Take a foot of stout iron wire and file it away in two long cones, till it is a thin wire in the middle. Now pass a current. This is exactly alike and equal at all parts, yet the middle of the wire will be raised by it to a white heat, while the ends are cool. This is not due to any difference in the current, but to the greater rapidity of the molecular motions involved, because effected in fewer molecules. Current is simply the number of such motions at each instant in each section of the conductor. Now for so-called "tension of the current." Take a wire of 1 ohm resistance, place it in a circuit of a large single cell, setting up 1 ampère of current. The difference of potentials between the two ends of the wire is 1 volt. The difference of potential between the middle of the wire and the – pole of the battery will be about 1 volt. Now place this same wire in the circuit of, say, 2,000 cells, close to the + pole of the battery, and with such resistances besides as will send 1 ampére current through. We have here the same current as before in all respects, and there will be the same fall of potential of 1 volt between the ends of our wire. But between its middle and the – pole of the source there may be 2 or 3,000 volts difference of potential, and it would be dangerous to touch. But this, again, is due to no difference in the current, *as current*, but to the sum of all the forces and resistances in the whole circuit; in fact, to a set of considerations with which the idea and the measurement of current have nothing to do. We are more likely to add to the number of units than decrease them; in fact, I see to-day that Sir W. Thomson has just proposed one, "mho."—SIGMA.

[52658.]—**Expansion Valve.**—This term has such a wide meaning, and includes such different varieties of valves, that it would, perhaps, have been better if the querist had stated definitely what kind of expansion valve he wishes to have information on. However, let us suppose that the query refers to what is generally called the back slide expansion or cut-off valve, which is in more general use than any other. The kind we will now consider has right and left-hand screws on the expansion valve spindle, for the purpose of adjusting the valves to cut off at any desired point, which may be done either by a hand-wheel, or coupled through a train of gear wheels with the governor. Another form of automatic expansion valve is controlled by the governor raising or lowering a slot link, and so shortening or lengthening the travel of the valve. Both the above arrangements dispense with a throttle-valve. In another form of valve the expansion is not made adjustable without altering the position or throw of the eccentric. We will not consider this kind of expansion arrangement. Our supposed engine is of the horizontal type, 5ft. stroke of piston, with slide-valves at each end of cylinder, and the cut-off adjustable from, say, one-twelve stroke to ¾ stroke. The screws on expansion valve spindle, though made to different diameters, must have the same pitch, and be made long enough to allow of the cut-off being altered to the extent named. Set the main valves first, giving the required amount of lead; then put the crank on dead-centre (say, with piston at back end of cylinder); take a wood lath, put one end against front cylinder cover, and measure or mark on the lath the inner edge of crosshead. Now get the labourer to turn the engine forward slowly, until the piston has moved 5in., which is one-twelfth of stroke; put in the expansion valves and couple up to the eccentric. The spindle should now be moved round until both the expansion valves are at equal distances from the ends of the screws on valve spindle, leaving, say, two or three threads to spare. Now move the excentric forward until the back expansion valve covers the steam port in the main valve. Secure the excentric temporarily, and move the engine round to the other centre, and repeat the process at that end. As a general rule, you will find the expansion excentric to be from 130° to 160° in advance of the main valve excentric. Now, having set the expansion valves for one-twelfth cut-off, if the screws have been correctly cut on the expansion valve spindle, turn the hand-wheel on the outer end of same spindle until the index points to any other later cut-off, and test again, and you ought to find all correct for that point of cut-off. If you have never seen expansion valves set, you may have a little difficulty at first; but it will come all right by-and-by. The advantages of expansion valves in an engine are very great. To state it shortly, they enable an engine to use up the steam to the greatest advantage; and if an engine with a given pressure of steam in the boiler can do a certain amount of work, any variation of that pressure can be easily compensated by a suitable alteration of the cut-off, instead of throttling or "wire-drawing" the steam. There are other advantages, too, which a little experience with the expansion valves will show you—all of them, however, valuable. If I have not explained the class of expansion valves with which you are acquainted, state what class they are, and I will do my best [illegible] you. LABOR OMNIA VINCIT.

[52650.] **Soft Spelter.** [illegible] kindly make that mixture [illegible] p. 431, and let us know the result? [illegible] the recipe out of a book, [illegible] once, and put less faith in the other recipes [illegible] [illegible]

[52650.] **Soft Spelter.**—If Mr. Hale has never tried the recipe that has taken up valuable space, he had better do so at once, and I [illegible] think he will be the first one. [illegible] that it would be a good way of brazing [illegible] be done, but can it? That's the rub. We live and learn. I did not know that [illegible] would make a workable alloy. I should be sorry to mix an ounce of silver with an [illegible], especially if money was short.—VOLT.

[52650.] **Soft Spelter.**—Last week a recipe was given for cold brazing of iron, consisting of "fluoric acid, steel filings, and brass filings placed in an earthenware jar." Now, as all chemists know, the fluoric acid would immediately attack the silicon of the pottery, and the mixture when prepared would do nothing, except produce ulcers on the hands of the one who is soft enough to prepare it. This hoaxing recipe, which appears in "Workshop Receipts," has been exposed several times in "ours," and I really think it is time that it should be tabooed altogether.—S. BOTTONE.

[52659.]—**Brazing without Heat.**—The old, old story of brazing cold, with fluoric acid, &c., &c., is once again "stumping the press," resuscitated after its death and burial, this time by John Hale, Univ. Coll., London. If he has ever used his own recipe, or has ever in his life seen any brazing done with the assistance of fluoric acid, &c., in an *earthenware* jar, will he send a sample, or sufficient proof of the fact, to the Editor? If this sample is on view at the office of the MECHANIC, I will pay John Hale, Univ. Coll., London, £5 for his trouble in sending it. The exhibition of the sample will be as good an advertisement to the MECHANIC as the presentation of a seven-roomed house has been to another paper recently. It is to be hoped, until someone has performed this feat so highly spoken of, that any further communications on the subject shall be added to the waste-paper basket. Once more will pennyworths of fluoric acid be in demand at the druggists' shops, many times more will the British workman make his fingers sore and use bad language, and once more shall we have numerous correspondents saying they have tried and failed. N.B.—When I was young and foolish, twenty five or thirty years ago, *I* tried, and failed, but omitted the bad language usually expended on this process.—THOS. FLETCHER.

[illegible]—**Cleaning Gaiters.**—Try a weak solution of ammonia and water before washing.—[illegible]

[illegible]—**Bartolozzi.**—The exhibition was held at the Savile Gallery, [illegible], Savile-row, Burlington-gardens, W., and was closed about June. It is now reopened as the Windsor Gallery School of Fine Painting. The exhibition was conducted by Mr. [illegible] Nash, who now carries on the [illegible] "X. Y. Z." to make application to him for the return of the picture.—[illegible]

[illegible]—**Dampproof Glue.**—Will "Archi[illegible]" [illegible] the method of preparing [illegible] readers?—[illegible]

[illegible]—**Cement for Pavement Lights.**—It [illegible]—[illegible]

[illegible]—**Bottle Batteries.**—[illegible]

[illegible]

[illegible]—**Zoned Chimneys.**—The chimneys [illegible] would be safe [illegible] small height, say [illegible] ft. [illegible] chimneys to [illegible] without extraneous support [illegible] that the extreme height above the [illegible] be not more than six times the [illegible] at the base.—[illegible]

[illegible]—**Steam Launch.**—I think "W. W. H." will [illegible] miles an hour out of [illegible] I think [illegible] information about all [illegible]—[illegible]

[illegible]—**Steam Launch.**—[illegible] at the rate of about eight [illegible] long [illegible] any speed approaching [illegible] the Thames it might be possible [illegible] from six to eight, but not more. If [illegible] he will find much [illegible] in Vols. XXXII. and XXXIII. [illegible] that a boat [illegible] and boiler big enough to drive it at 14 miles an hour.—[illegible]

[illegible]—**Chimney.**—I should advise "P. H." to consult a competent architect as to his proposed chimney. The Bradford accident was the result of amateur design and superintendence.—[illegible]

[illegible]—**Chimney.**—If "P. H." applied to the Secretary of Civil and Mechanical Engineers Society, 1, Westminster Chambers, most likely he could peruse the manuscript of a paper read before the society, which would give him all he would require in constructing his shaft.—T. BROCKLEBANK.

[illegible]—**Chimney.**—I do not know of any articles having appeared in these pages on chimneys. There were a few queries and answers a few months ago. The best and only good work I know on chimneys is "Boiler and Factory Chimneys," by R. Wilson, C.E., published by Crosby Lockwood and Co., [illegible]. Molesworth gives a few lines also.—BOSWELL.

[52726.]—**Fishing Flies.**—The back and neck feathers of the golden plover are used to make "the golden plover hackle"—a good summer fly for trout. Thick shellac varnish is the best for making the heads of flies—merely shellac dissolved in spirits of wine.—FAL.

[52727.]—**Quantity of Water Used per Hour.**—The following rules are from Molesworth's Pocket Book:—Multiply the pressure per square inch by 2·307, which will give the head of water in feet. The velocity per second must next be found by the following rule: $8·025\sqrt{\text{Head}}$. To find the quantity, multiply the area of the aperture in sq. ft. by the velocity per hour, the result will be the number of cubic feet used per hour, which, multiplied by 6·24, will give the quantity in gallons per hour.—ROWLAND GASCOYNE, Conisbro, Rotherham.

[52731.]—**Axle of Plate Machine.**—Why would not metal do? as "H. H." himself asks. Nine out of ten are made of metal, with a fixed and a screw flange to grip the glass. Glass would be useless, as it would snap; and ebonite would not wear at the bearings unless cased in metal. Vulcanised fibre would be stronger than ebonite.—SIGMA.

[52731.]—**Axle of Electrical Plate Machine.**—What makes you think a metal axis won't do? You are mistaken, anyhow. A brass rod answers best, fitted with a fixed cap at one side of the plate, and a screw to enable the other cap to be screwed tight on the other side. Two pieces of thick cloth are placed between the caps and the glass plate, one on each side, to prevent smashing the glass by too much pressure. For the same reason the movable cap must not be screwed on too tight.—R. A. R. BENNETT.

[illegible]—**Axle of Electrical Plate Machine.**—The axle is usually constructed of metal. Three-quarters of an inch is ample diameter. Two metal cheeks, one of which can be screwed down against the glass plate, is the usual way of fastening the plate to the axle. A little warm electrical cement [illegible] just before screwing up. The metal [illegible] may be cased in an ebonite tube if desired; but the [illegible] difference is very slight. Such a [illegible] without rings, will give a [illegible] spark; [illegible] diameter, 4 to [illegible] spark.—[illegible]

[illegible]—**Permanganate Stain on Carpet.**—[illegible] sulphide [illegible] the carpet might be [illegible] most harmless [illegible] which [illegible] permanganate [illegible]

[illegible]—**Finding Speed of Trains.**—[illegible]

that the diameter of the driving wheel is [illegible]. For instance, an engine has a driving wheel the diameter of which is 8ft., the circumference is [illegible] times the diameter, therefore the circumference is equal to $\frac{176}{7}$ft., the distance which the engine will travel in one revolution of the driving wheel; in 12 puffs it will have travelled [illegible]; say, for example, that it travels $\frac{176}{7}$ft. per second, that is approximately 25 yards per second, then the speed of engine is equal to 50 miles per hour.—SIGNAL BOX.

[52733.]—**Finding Speed of Train.**—[illegible] Webb's compound engines have one low-pressure cylinder, consequently, there are but two [illegible] puffs for each turn of the wheel. To estimate the speed of a train from the "puffs" of steam would indeed be an incorrect method. In the first place, at high speed, they would be difficult to count; [illegible] better take the number of times a connecting rod comes to a certain position. To find the revolutions a wheel will make per mile divide 1,680 by the diameter of the wheel; thus $\frac{1680}{8} = 210$, showing that an 8ft. wheel revolves 210 times per mile, and, of course, the same number per minute when the train is running at a speed of 60 miles an hour.—HISTORIAN, M.I.M.E.

[52733.]—**Finding Speed of Train.**—"C. R. R." will find it rather close work, [illegible] beats of a locomotive accurately, when they are as frequent as 11 or 12 a second. However, a little calculation shows he has been nearly right—that is, of course, supposing the wheels do not slip. Thus the 8ft. wheel will be 25⅛ft. in circumference. Multiplied by 11, gives 276⅜ft.; divide this by 4, number of beats to a revolution, gives feet per second as 69 and a fraction. As 88ft. per second equal 60 miles per hour, 69ft. in the same time would be 47 miles per hour, as near as may be. Is "C. R. K." quite sure he is not enjoying a quiet smile at our expense? While on this question of speed, perhaps the following table may be of interest, as showing what man has done in the way of obtaining celerity of transit by mechanical means in the locomotive engine, in comparison with the rapid motion of the air, the progressive power of his friend the horse, and his own poor, feeble, unaided efforts in walking:—

Miles per Hour.		Feet per Second.
60	Speed of wind in hurricane, and of very fast express trains ..	88
50	Hurricane........................	73⅓
45	Running time of express trains	66
40	Tempest	58⅔
35	....	51⅓
30	....	44
25	....	36⅔
20	Horse's gallop; brisk gale	29⅓
15	Gale; fast trotting horse......	22
10	Speed of a good trotting horse..	14⅔
7½	....	11
5	Gentle, pleasant wind; fast walking........................	7⅓
*4	Ordinary walking	5$\frac{13}{15}$
*3	Slow walking	4⅖
2	....	2$\frac{14}{15}$
1	Wind hardly perceptible	1$\frac{7}{15}$

* It has been stated as the result of careful experiments, that the least exhausting and best pace for adult males is 3½ miles per hour.

—R. W. J.

[52734.]—**Paper Tubes.**—Cut strips of ordinary cartridge paper, the same width in inches you want the tubes to be long, and about a yard in length; cover them evenly with strong paste containing glue, and then wind tightly round cylinders of wood turned to the required length and diameter of inside of tube, taking care to leave the first fold or lap without paste, so as not to adhere to the smooth roller. Let get quite dry, and then extract cylinder by tapping one end with a hammer.—JOHN HALE, Univ. Coll., London.

[52735.]—**Coloured Pencils.**—The colouring matter consists of mineral red chalk in the one case, cut into slips with a saw, and in the other of soluble Prussian blue with whiting.—JOHN HALE, Univ. Coll., London.

[52737.]—**Steam Boiler.**—Your query is very vaguely worded. Give dimensions of a boiler, class of work you want it to do, and pressure you wish it to carry: I will then answer you fully. Plain egg-ended boilers are great fuel wasters, compared with the Cornish and Lancashire types.—J. F. W.

[illegible]—**Steam Boiler.**—The egg-ended boilers are certainly the safest and most durable when everything is taken into consideration. Even in so small a boiler as 3ft. diam. it ought to be either strengthened by stays or ribs; but we must not forget that a boiler with flat ends made extra strong is liable to bulge out, under internal pressure, at the centre—that is, to assume a barrel shape. Those who have given considerable attention to this subject state that the flat ends of tubular boilers ought to be in one piece, either solid or [illegible].—ROWLAND GASCOYNE, Conisbro, Rotherham.

[52737.]—**Steam Boiler.**—Is "Steam" speaking about toys or boilers? or is he laying a trap to let someone (or perhaps himself) fall into? Toy boilers are seldom made egg-ended, while working boilers often are. Toy boilers are often made flat-ended without stays, while working boilers are most frequently made with flat ends efficiently stayed. In speaking of a square end, I presume "Steam" means flat end; but the safety of a boiler depends on other points as well as form of ends, as the form of end affects end safety only. I may inform "Steam" that a flat unstayed end of given area and thickness is much weaker than an egg-shaped end of equal thickness and area, consequently flat ends are never put in without staying them, except in very small boilers or toys. Egg-shaped ends are rarely stayed; but to fully explain this query would require more space than our editor would be willing to give on a query which would only interest a few; but if "Steam" will put such queries in a clearer form I will give him the benefit of my experience.—BOSWELL.

[52738.]—**To Fasten Fan Blades and Arms on Spindle.**—"Sandy Sam" must have a boss cast, with arms on, in gunmetal. Put a print on pattern, or bore hole through casting to fit spindle, and secure with a set screw. Two arms will be enough. If for a fan, make the fans out of thin iron, and turn up at the sides to catch the air.—VOLT.

[52739.]—**Electric Bell.**—Several forms of door contacts are made which will ring the bell whilst the door is being opened only. They are fixed upon the frame above the door in such a position that the top of the door touches the drop-piece as it passes. The length of time the bell is wanted to ring can be regulated by the distance at which the drop is fixed from the joint of the door. If at 6in., the bell rings when the door is opened 2in., and stops when open 2ft. If you want a good battery without porous cell, use the original form of Leclanché's agglomerated battery.—R. T. LEWIS.

[52740.]—**Drying Damp Room.**—The simplest way to dry the room is to put a flue in, so that a current of air can be got through it. The only other way is to place a large tray containing dry chloride of calcium in the room, and as this takes up water and becomes fluid, to evaporate it to dryness again over a fire or powerful gas-burner. This will be a great deal of trouble, and not so effectual as a good flue.—THOS. FLETCHER.

[52743.]—**Lathe Saddle.**—The information "Q." desires is already in MS., forming a portion of the eighth and supplementary chapter on "How to Make a Cheap Lathe," and will shortly be in type. I think that he will find it contains all necessary instruction; but if not exactly the thing required please say so, and I will write again.—J. H.

[52744.]—**Marble.**—Let me recommend the following to Mr. E. Beaumont:—(1) Take 2 parts soda, 1 of pumicestone, and one of finely-powdered chalk, sift these through a fine sieve, and mix them into a paste with water. Rub this well all over the marble, and probably the stains will be removed; then wash it with soap and water, and a beautiful bright polish will be produced. If this does no good try the following:—(2) Clean with diluted muriatic acid, or warm soap and vinegar; afterwards heat a gallon of water in which dissolve 1½lb. of potash, add 1lb. of virgin wax, boiling the whole for half an hour, then allow it to cool, when the wax will float on the surface. Put the wax into a mortar and triturate it with a marble pestle, adding soft water to it until it forms a soft paste, which, laid on the marble and rubbed when dry with a woollen rag, gives a good polish.—JOHN HALE, Univ. Coll., London.

[52745.]—**Furnace.**—My opinion is that your work can be done in an ordinary fire with the bellows. I think the fault is with you, by forcing your fire too quick, thereby burning the outside before the inside is at a welding heat. I have welded 4in. square bars in an ordinary fire with ordinary 36.n. bellows worked by hand. I have tried the fan-blower, but since have had 24in. double blast bellows, which I think is the best thing for good work: they are noiseless and easy to work. Should be able to do it with coal, but certainly fire would be clearer by using breeze.—ALBERT HALL, Weston, near Honiton.

[52746 and 52750.]—"**Edco**" **Battery**.—Each box of "Edco" battery will give 4 volts and 5 ampères steadily for 90 hours; this would only give sufficient energy for lamps of about 1½ candle-power. With 3 "Edco" boxes, 3 lamps of 5 candle-power can be lighted 126 hours at a total expense, including zinc consumed, of 7s. 6d., or 1 farthing per lamp per hour. Lead lining is used in preference to glass, vulcanite, or earthenware, from its non-liabilty to crack from heat or rough usage. There is, of course, no necessity to insulate the carbon plates from the lead, as they would even in that case be joined by their proper connections, as well as by the liquid.—C. R. H.

[52751.]—**Recovering Silver.**—The best way would be to dissolve the bits of iron in nitric acid, which would dissolve silver and all; the silver could then be precipitated by mixing this solution with hydrochloric acid till no more ppt. is formed. The ppt. is then washed to get rid of nitrate of iron. When dry, mix it with twice its weight of carbonate of soda, one-tenth of its weight of potassium nitrate, and a little borax to act as a flux. This mixture is to be put little by little into a red-hot crucible, and heated red-hot for about a quarter of an hour, stirring it occasionally; after which the contents of the crucible are poured out on a piece of slate. The silver will be found to have collected at the bottom of the crucible, and must be freed from soda carbonate, &c., by breaking it off with a hammer and washing with hot water. This is not very much trouble, I think, and all the silver would be saved this way if the operation is carefully performed. I recommend this to the notice of chemists who don't know it already, as if all the precipitates made by silver nitrate are treated in this way, the same amount of silver can be made to last almost *ad infinitum*, which, as it is an expensive substance, is quite worth doing.—R. A. R. BENNETT.

[52752.]—**Clock to Strike by Electricity.**—The first part of this question was answered (with a diagram) on page 372 of present volume. The wires would, of course, have to be longer if the clock was in another part of the house; but this would make no difference to the arrangement.—R. A. R. BENNETT.

[52752.]—**Clock to Strike by Electricity.**—Several answers have been given lately to this question. The simplest plan is to arrange a contact actuated by the lifting of the hammer of the clock; either let the hammer itself be in circuit and close it by merely touching a light spring, or arrange two springs insulated from each other, and placed close to the hammer, so that as it rises it brings them together. It would be waste of time and money to try to regulate existing clocks from a central one, seeing that it would be cheaper to make new ones, with a mere system of hands and their gearing, driven altogether from the clock.—SIGMA.

[52757.]—**Silvering Solution.**—Potassium cyanide argento, or, as Mr. J. Hales remarks, otherwise silver solution, will leave a deposit of silver on base metal such as brass and copper, and it is done in this way: Take ¼lb. of cyanide of potassium, and ½oz. of nitrate of silver; dissolve all the cyanide in 16oz. of distilled or boiled water, and the silver in a similar quantity in another vessel. Into the vessel containing the silver throw a spoonful of common salt; stir this up well with a clean piece of wood, and let it settle; dissolve some salt in water, and after the silver solution is settled mix a few drops of the salt water in it. If there is any cloudiness formed, it proves that all the silver is not thrown down, and more salt must be added, and then stir and allow to settle. If the addition of salt water has no effect, the water may be decanted off, carefully preserving the white deposit. Now pour some boiling water on this deposit, let it settle, and pour off as before. Do this at least three times, pour off as dry as possible, and add a pint of clean boiled water, and then, by ¼oz. at a time, the cyanide solution, till all the white precipitate is dissolved; add enough water to make half a gallon; stir well after each addition of cyanide solution. If on dipping the article, which must be well cleaned with brickdust and water, into this solution, the silver deposits on immediately in a dark powder, it must be weakened by adding more water; if it coats too slowly, more white precipitate must be prepared, washed, and added to it. This must also be done when the solution is getting short of silver. It works best at about 60° or 70° Fahr., and a dry warm room helps the operation. This method gives a most beautiful result when the work is polished and burnished.—JOHN HALE, Univ. Coll., London.

[52760.]—**Safety Valves.**—You will find the following rule easy and accurate. When load and pressure are given we have for length of lever—

$$L = \left\{ \left(P \times A \right) - \left(V + \frac{w \times g}{l} \right) \right\} \frac{l}{W}.$$

Where—

L = distance between weight and fulcrum.
P = pressure in lb. per square inch above atmosphere.
A = area of valve.
V = weight of valve.
w = weight of lever.
g = distance of centre of gravity of lever from fulcrum.
l = distance between valve centre and fulcrum.
W = weight of ball.

—J. F. W.

[52760.]—**Safety Valves.**—This query is very indefinite. A safety-valve can be had in a hundred different forms, each of which would require a different mode of calculation. Supposing the valve to be of the ordinary lever construction, the working out would be as follows:—A = total pressure of steam on under side of valve; L = length of lever; F = fulcrum of lever; and W = weight of ball hung on lever. W and A are in pounds, F and L in inches. (1) $\frac{L \times W}{F} = A$, and (2) $\frac{W \times L}{A} = F$, and (3) $\frac{F \times A}{W} = L$, (4) $\frac{F \times A}{L} = W$; so that from the foregoing formulas, any of the four items can be found. This does not take into consideration (which I consider to be balanced) the lever and valve. If "Phonographer" will give details of his valve, I will give it my attention; or advertise his address, and I will correspond. The proportion of valve area should be about ¾ square inch to each square foot of firegrate.—BOSWELL.

[52760.]—**Safety Valves.**—It is necessary, first, to ascertain the pressure caused by the weight of the lever alone. This may be done by the following method, if the valve is an ordinary lever safety valve:—Multiply the weight of the lever by half the leverage, and divide by area of valve. The product is the pressure per square inch. Subtract this from the intended blowing-off pressure, and the remainder will be the pressure that must be provided for by ball weight; hence, multiply this by area of valve, and divide by the weight of the ball. The product will be the leverage required, which multiplied by distance from fulcrum to valve spindle gives the distance from fulcrum to ball.—ENGINEER, Dewsbury.

[52760.]—**Safety Valves.**—The rule for adjusting the safety valve of a boiler is as follows:—Let W = weight at end of lever, L distance between weight and fulcrum, w weight of lever, g distance of centre of gravity of lever from fulcrum, P = pressure of pounds per square inch above atmosphere, V = weight of valve, A = area of valve, and l distance between valve centre and fulcrum, then—

$$P = \left\{ \frac{(w \times g) + (L \times W)}{l} + V \right\} \div A$$

$$W = \left\{ (P \times A) - \left(V + \frac{w \times g}{l} \right) \right\} \frac{l}{L}$$

$$L = \left\{ (P \times A) - \left(V + \frac{w \times g}{l} \right) \right\} \frac{l}{W}$$

When the lever is prolonged beyond the fulcrum, and provided with an adjustable weight, the following simple rules may be used—

$$P = \frac{WL}{Al},\ W = \frac{PAl}{L},\ L = \frac{PAl}{W}.$$

Trusting the above will be useful to "Phonographer" and others.—ROWLAND GASCOYNE, Conisbro, Rotherham.

[52762.]—**Hens Losing Feathers.**—A roosting-place too small, if shut up close, would be too warm and suffocating unless well ventilated at top, and if dirty, would be most unhealthy and full of vermin, causing loss of feathers. But a small roosting-place is better than a large one, if it be whitewashed with hot lime occasionally, cleaned out with a trowel every morning, and dry ashes or earth spread on floor. Perches may be only 6in. high; ventilation at top is essential. If your hens have vermin, let them have plenty of dry ashes with flowers of sulphur mixed through. Your two meals of Indian meal twice a day is too much if the fowls have plenty of field space. One meal at evening of oats, barley, or small wheat, &c., should be enough. See that they have fresh water every morning, and lime or plaster to pick at; also a small shelter from rain, and keep no fowl exceeding 19 months in age, or any hatched after April.—W. DODD BECKETT, Dublin.

[52764.]—**M'Naughted Engines.**—M'Naught was an engineer who pieced out the power of the old mill beam engines, providing a higher pressure of steam and a cylinder to work it in before entering the old cylinder at the old pressure; consequently, a beam engine which has been compounded is called a M'Naughted engine. Stamper valves are opened and closed almost instantaneously, whereas the slide-valve movement is much more gradual by the eccentric motion.—J. F. W.

[52764.]—**M'Naughted Engines.**—Are beam condensing engines, to which a non-condensing cylinder has been added, generally at about half distance between beam centres and the crank? The engine then is a compound. This plan is often carried out when the engine becomes too small for the work required; but occasionally new engines are made on the same plan. A stamper valve is a double-seated equilibrium drop valve. Cornish valves are sometimes miscalled stamper valves.—LABOR OMNIA VINCIT.

[52765.]—**Prevention of Electric Sparks.**—Wind outside the magnet-coils another circuit of high resistance, with its ends soldered to those of the magnet wire, as a shunt. Instead of a spark on breaking contact, there will be a current in this wire.—SIGMA.

[illegible]—**Prevention against Sparking in Electrical Contact Breakers.**—There must be something wrong with the platinum, surely. The use of platinum for contacts is to prevent this very occurrence, if I am not very much mistaken. It has never happened to my apparatus. If "Sigma" answers this question, I expect Mr. Sprague will [illegible].—R. A. R. BENNETT.

[illegible]—**Magic-Lanterns.**—Oil lanterns can be worked one above the other by using a bent chimney for the lower one; but I think there is no advantage in so arranging them, and that the old plan of using the lanterns side by side is more convenient. For registering effects the slide carrier introduced by Mr. Chadwick, of Manchester, is excellent if the slides are unframed; but if framed, the only way is to register them by trial on the screen. and make such marks, use stops, packings, &c., as may be found necessary, either on the slide frame or lantern fronts. This necessitates a great amount of care, and a considerable expenditure of time if anything like a good result is desired, and thorough rehearsing is necessary before giving an entertainment. I am told that Mr. Malden takes all the summer to register the effects for his winter exhibitions.—DITTON.

[52769.]—**Dynamo.**—To S. BOTTONE.—If made twice the size. and driven at 3,000 revolutions per minute, it will light well six 10-candle Swan's lamps. Every part should be double the size except the wire, and that might be 7lb. of No. 18 on each leg of the field magnets, and about 1lb. do. on the armature. But this form of machine does not do for continuous work: it gets too hot. (See also 52776).—S. BOTTONE.

[52770.] — **Grandfather's Clock.** — If "D. W. W." examines the fly, he will probably find the holes very much worn, so that fly train does not start off. Or possibly fly pinion is much cut as well. If so, put fresh holes, and shift wheels below to run on another part of pinion. Large holes, however, will alone account for it.—A. E. B.

[52772.]—**Tinning Bright Steel Goods.**—The tinned surface is rendered bright by friction. The bath may be retained at the proper strength by small additions of fused protochloride of tin.—JOHN HALE, Univ. Coll., London.

[52773.]—**Waterwheel.**—The amount of water that the 5in. double-acting pump would deliver would be useless unless you could get a very high fall; and if you had to force it up a suitable elevation, the power given out would not repay the cost of pumping it up.—LABOR OMNIA VINCIT.

[52774.] —**Strabismus.**—I have not said that electricity is applied to the muscle of the eye. What I said was that if electricity is applied it should be only under skilled advice. If the spectacles are of no use, a simple surgical operation, which I suppose is scarcely felt, effects a cure.—S. M P.

[52775.]—**Dynamo.**—To S. BOTTONE.—If made half as large again, and wound with 5lb. No. 16 on the magnets, and ½lb. of 18 or 20 on the armature, you would be able to light four 10-candle Swan lamps on the lathe: but you must so arrange the rigger and driving wheel as to get at least 3,000 revolutions per minute. But you will find it hard work, and such a dynamo cannot be run for more than 20 minutes without getting dangerously hot. —S. BOTTONE.

[52776.]—**Dynamo.**—By a printer's error (I presume) my query says "three or four hours daily equal to 10 c. p. Swan incandescent lamps:" I meant to say "fifty 10 c. p. Swan, &c."—JOHN HALE, Univ. Coll. London.

[52776.]—**Dynamo.**—If you will take my advice you will construct a machine on Heinrich's principle. It is fully illustrated in Vol. XXXIII. p. 28. If you will kindly state how many 10-candle lamps you require to use, I will give you the information required as to horse-power required, and size of dynamo, wire, &c.—S. BOTTONE.

[52778.]—**Dissolving Views.**—See answer to 52766.—DITTON.

[52778.]—**Dissolving Views.—Registration of Effect Slides.**—My way to register is to mount effect slides in separate single carriers, after which I place them in the lanterns and make them register (by cutting the carriers or glueing a piece of wood on); then I make a notch, or knock a piece of wire in the top part of the carrier, so that I cannot put them further in the lanterns. If the object glasses are in focus, they should always register. I prefer using separate views for day and night, and always (when circumstances permit) use the single-drop carrier, with opening at top for ordinary slides, and by the dissolving tap light up the next lantern *very faintly*, which enables me to see, long before the audience would notice it, if the slide registered properly, if not a little movement one way or other soon puts it right. Mr. Malden has his slides mounted in single carriers, and are *made to register* properly when first mounted in *the carriers.—E. R. SHORT.*

[52780.]—**Bath Heater.**—J. H. Humphriss apparently has an exceedingly poor gas supply. To heat 40 gallons of water from 50° to 98°, say, in twenty minutes, he will need a ¾in. bore gas main. If he will communicate with me, and state what his gas supply is, I will set him right.—THOS. FLETCHER, Museum-street, Warrington.

[52780.]—**Bath Heater.**—In reply to J. H. Humphriss, I wish to state that I have had fitted a number of baths, full size make, the water of which has been raised from a temperature of sixty degrees to upwards of ninety in from four to seven minutes, 45 gallons. The baths were manufactured by the late Nathan Defries, of the Euston-road, and cost about fifteen pounds, the boiler consisted of thin flat copper tubes, tinned, and about 4ft. long, in number about 12, and 2in. wide, connected to a similar tube at each end, and placed side and flat ways alternately. The boiler was fixed to the bottom of bath by means of two large union joints, and about 2in. distant from it. The burner was made from round copper tubes, the same length as boiler, and as many tubes; it was pulled out at foot of bath and was attached to an indiarubba tube. The quantity of gas burned would cost about twopence.—W. R. BOUSFIELD.

[52781.]—**Battery for Lamp.**—I use similar battery, though not for lamps. By your description it appears as if the carbon (i.e., 1in. square) was in the porous cell. Again, your surface does not agree with "E. F. F."s. Carbon should be at least as wide as the zinc, and should be placed in outer cell. I am rather in favour of chloride of zinc for porous cell, though ch. of am. certainly keeps the zinc cleaner.—R. HANNEN.

[52781.]—**Battery for Lamp.**—Mr. Hargreaves is only experiencing what everyone else does, who, in spite of warning from those who know the facts, endeavours to get light from batteries. There is no battery in existence which does not make the cost some twenty times that of gas, in addition to the trouble; and, what is more, there never will be, unless the products are of value, and that never will be on any large scale, because the market would be at once glutted.—SIGMA.

[52782.]—**Dynamo.**—Does "Wag" work his dynamo while the battery is coupled up to the magnet? If he does, and the magnets are properly worked and connected, he ought to get about sixty ampères of current. But I suppose he is working it as a circuit dynamo, without the battery. Then the size of wire on the armature is certainly too small, and the quantity too great. Put only 2lb. of No. 18, and you will probably get a better result. Are you quite sure that you have connected it right up, and that you are not sending the current round the magnets in such a way as to get reversed poles. Four magnets are very unusual for a Siemens' H girder armature.—S. BOTTONE.

[52784.]—**Pedal Reeds to Harmonium.**—It seems unnecessary to furnish instructions how to make a harmonium pan, as the information has very recently appeared in the "E. M.," through the kindness of Mr. S. Mayer. I cannot exactly refer to number in which the information appeared, but if I remember right, it is in the last volume but one—viz., Vol. XXXVI. This, with the information furnished below, will, I believe, be all that is required by the querist. Make the channel for the lowest bass note—viz., 16ft. C, 6in. long and 1in. deep, and in width ⅛in. wider than the vibrator. The 8ft. C may be 5in. in length, ¾in. deep, and in width a trifle wider than the vibrator. All the other channels may be made in proportion to this; but each channel should be spaced out to suit the compass of the pedal board. To accomplish this, it is merely necessary to have wider divisions between each channel or tube to that which is employed in the construction of an ordinary harmonium pan. When "Station Master" has completed his pedal action, I should be exceedingly obliged if he would make known the result of his undertaking, and if any difficulties occur previous to this, if he will kindly state what they are, I will endeavour to help him to remove any difficulty.—G. FRYER.

[52786.]—**Tricycle Crank.**—Long cranks in practice are found to be very fatiguing, and from long experience of cycling, I should not like to recommend them to anybody. If "J. K. T." will send full particulars of the machine he intends ordering, with its weight, height of wheels, and whether geared up or down, and pattern, with particulars of himself, and the purposes to which he intends putting the machine, I will help him.—S. RICE.

[52787.]—**Boiler Query.**—If your mud covers are of the common type—viz., held against the boiler by a crosshead—make the joint with horse manure; but should they be cast-faced covers, fitting against a cast-faced mouthpiece, make them with small copper wire, or ⅜in. dia. composition gas-piping.—J. F. W.

[52787.]—**Boiler Query.**—If the boiler is working exactly under the same conditions as before, and with the same attendant, then I should think the fault lies with the jointing materi[illegible] all events, if the surfaces are planed or turned, y[illegible] might try asbestos tape, as advertised in [illegible] or lead wire.—LABOR OMNIA VINCIT.

[52787.]—**Boiler Query.**—Perhaps "A. G." h got his ropeyarn too thick, and that will allow to burn away and cause them to blow; and if th ones do not answer, let him try some sheet zinc and cut some joints out of it; put tallow or whi lead on them; the former is the best to leave t lid and boiler when being changed.—PHOT GRAPHER.

[52787.]—**Boiler Query.**—If mudhole joints ha been made good with hempen rope and red and whi lead, they should be so again, unless the rope is b and rotten, or the edge of mudhole is weakened l wasting from corrosion, which I know is ve common about these holes. If the plate is wast at edge of hole, it will spring in tightening u Try Asbestos millboard cut to shape, after bei soaked in boiled linseed-oil from six to twelve hour The cause and remedy can only be given on e amination by a competent inspector. You say th used to stand for months. I assure you they woul not stand so many months for me, as they shoul be opened at least every three months for cleanin and examination, however favourable the workin conditions. The fault may really lie somewher here, in slight defects having crept on unobserved —BOSWELL.

[52787.]—**Boiler Query.**—To "A. G."—I seems rather strange to me that your mudhole doo should keep tight three or four weeks, and then begin to leak. Do you use anything to prevent boiler from scaling? I once knew a case where I could keep the joint quite tight until I commenced using common soda as a preventer from boiler scaling. Then I was obliged to get a new block put on, and mudhole door to suit. I suppose your faces will be good, as you have had the boilermaker to examine it. Then I should try a joint as follows: From an old indiarubber bucket or live ring valve, cut a strip, say, about ¼in. or ⅜in. thick the required length, and join the ends together by a piece of twine, and get some blacklead and make into a paste: then put well on to the block face, and likewise the rubber (to prevent sticking). I think you will find it makes the best and cheapest joint in use; in fact, I have some that have been in use four or five years, and always tight.—FIRER, Dewsbury.

[52788.]—**Papier - Mache Ornaments.**—1. The pulp is boiled in a solution of gum arabic or of size. 2. The pulp is poured into the previously oiled moulds and then pressed with a counter mould to make the cast nothing more than a crust or shell as in plaster casts. 3. The moulds are either o wood or metal. 4. Directly the pulp is a little se the casts are black varnished and then placed in a heated oven.—JOHN HALE, Univ. Coll. London.

[52788.]—**Papier Mache.**—To make papier maché, the pulp is mixed with a solution of lime starch, or gum, and it can also be mixed with san of various kinds, chalk, &c. It is then pressed int the required shape, and linseed oil is spread ove it. The next step is to bake it; and, lastly, it i varnished. Metal moulds would be the best bot for standing the heat and giving a good, clear impre sion of the article required.—W. HENLEY RICHMON

[52790.]—**Indiarubber Gas Tube.**—The onl really effective remedy to prevent rubber tub smelling is to cut some strips of tinfoil, wrap them closely round the tube, and wrap tape outside thi to prevent the tinfoil getting damaged. A coat o varnish on the tape will make it secure; but th result is a very stiff tube. The best way is to us composition, lead, or brass tube, and use rubb only for coupling, or for such parts as require to b constantly bent.—THOS. FLETCHER.

[52791.]—**Indiarubber Gas Tube.**—This ques is answered by "Nun. Dor." on page 71 (No. 9 of present volume. It is, however, unsatisfacto for the parties concerned, as he says that there no remedy, and special tubing ought to be procure I think, however, before giving it up as a bad jo I would try varnishing the tube with two or thr coats of varnish: say shellac dissolved in naphth I don't believe any smell would get through thi At any rate, it is worth trying.—R. A. R. BE NETT.

[52794.]—**Toning Prints.**—Do not print un you get a purple-black, but a darkish shade of re and then tone with any of the multifarious solu tions used for the purpose, until your pictures ha a blueish-purple tint. This will allow for a slig return of the raw umber colour in fixing.—JO HALE, Univ. Col., London.

[52797.]—**Joining Electric Wires.** — I ha always found that simply bending the two wi round each other answers perfectly well. T indiarubber or silk should be cut off the ends of t two wires, and they should be twisted togeth several times to make sure that the surfaces are contact. After this, paraffined silk should be wou round the join. I believe joints made in this w are really quite as good as when soldered; but n of course, so strong.—R. A. R. BENNETT.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

Since our last "Ditton" has replied to 52067; "London Stone," 52258; W. J. Grey, 52389, 52430.

QUERIES.

[52799.]—**Microscope Eyepiece.**—I have been trying to grind a lens for the eyepiece of a microscope, but have not quite succeeded to my satisfaction. Will Mr. Lancaster, or other reader, give me a few hints?—(1) After rough grinding in the lathe, should the lens be finished and polished in the lathe, or by hand grinding in the metal "tool"? (2) If in the lathe is it better that the lens should revolve in the lathe, or the tool, and the lens held in the hand? (3) I find my concave tool alters in radius during the process of grinding. How can this be prevented? (4) As the proportion of the eyelens to the field lens is as 1 to 2, is it necessary that this ratio should be exactly maintained, or only approximately? (5) After the lens is finished and polished, how can I ascertain its exact focus?—Micro.

[52800.]—**Insulation.**—Will any of "ours" kindly mention a work on the manufacture of guttapercha and indiarubber for insulating purposes?—Megohm.

[52801.]—**Examinations.**—Will any reader be kind enough to recommend the best textbook for the Honours Grade in Electric Lighting and Transmission of Power in the City Guilds Examination?—Megohm.

[52802.]—**Blueing Cotton.**—Will Mr. A. H. Allen, or any correspondent, oblige by saying how to give the blue shade to bleached cotton yarn and calico after leaving the bleach bath without being spangled?—Bleacher.

[52803.]—**Tuning Forks.**—How made? How tempered? whether hard or soft? sort of steel? how tuned? tuned before or after tempering? size of forks for Lissajous' experiments? size and shape of prongs? how small mirrors are made and fixed? should forks have holes for that purpose? should handle be screwed for fixing to stands, &c.?—Phosphorus.

[52804.]—**Kaleidophone.**—Best form of? size and length of rods? how fixed to foot? reflecting heads—where can they be got? is the foot best of metal or wood?—Phosphorus.

[52805.]—**Weber's Wave Canal.**—Wanted dimensions of?—Phosphorus.

[52806.]—**Steel Bronze on Brasswork.**—How is this appearance produced?—Phosphorus.

[52807.]—**Power for Circular Saw.**—Any advice upon the following gratefully received. A mile of 3in. internal diameter iron piping taps a lake of 10acres area at an elevation of 200ft. above its lowest end. The course of this pipe passes over two undulations, the last of which is only about 80ft. below the level of the lake. An oscillating water engine at the lowest point in the main (where the registered pressure is 90lb. per sq. in.) has on trial failed to give any approximate power through the negative friction in the long length of piping. Would this diameter of piping provide a volume of water sufficient for a turbine or overshot waterwheel to develop, say, 8 horse-power for circular sawing machinery, and what would be the minimum size of each?—considering that economy must be studied in the choice of either turbine or wheel.—Shadowless Man.

[52808.]—**Knocking Inside Cylinder.**—Will any practical engineer give me any information as to the cause of knocking inside cylinder? It is a low-pressure beam-engine, Mather and Platt's piston. After a careful examination, I find that the brasses and gearing are tight and firm; but when two-thirds of the weight is taken off, and sometimes even when the full weight is on, I find that there is a constant knock or bump when the piston is at the bottom only. The engine is 108 indicated horse-power, 6ft. stroke, 29 revs., 40lb. pressure, cyl. 32½in. The valves are lifted by cams; the top valve has ¼in. lead, 5-16 lift = 9-16 lift; bottom valve 3-16in. lead and 3-16 lift = ⅜ lift; steam cut off at one-third of stroke; exhaust opens two-thirds of stroke. And also as to what will be the result if the air-pump foot and delivery valves are leaky and bad? And what is the result if the air-pump draws much air through the gland? Any information will oblige.—Engineer Jack.

[52809.]—**G. E. R. Goods Engines.**—Various illustrations of these engines appeared in last volume, but will not Mr. Brewer, or other correspondent, give some of the chief dimensions, without which illustrations are little good? Can any correspondent also give chief dimensions of the rebuilt 7ft. 2in. singles, such as 299?—Le Bœuf.

[52810.]—**Jam.**—I shall be greatly obliged for any information relative to the manufacture of jam on a business scale—details of process, plant required, and cost of same. Could it be made profitably in the country?—A. B. C.

[52811.]—**Empire Work.**—Can any reader kindly inform me by what process the gilding was done on clocks, candelabra, &c., during the first French Empire period? Detail would oblige.—Nap.

[52812.]—**How to Cause Tar to Dry Quickly.**—Could any of your readers suggest a treatment of ordinary coal tar to cause it, when applied to any surface, to dry quickly? Is there any cheap chemical I could add that would answer the purpose?—Inquirer.

[52813.]—**Boiler for Model Engine.**—I have a small engine, cylinder 2in. stroke 1in. bore. Will some one kindly tell me what would be the cheapest form of boiler (and size) to work the same well? Must it necessarily be riveted? I should also be glad to know probable cost of getting one made.—J. E. H.

[52814.]—**The Clun Stone Circle.**—It will perhaps be remembered that some 18 months since "F.R.A.S." kindly gave me some information, by the aid of which I hoped to ascertain whether the overthrown monolith, now lying some 120 yards towards the S.E. of this circle, was duly in line with the point of lowest sunrise, as seen from the centre of the circle. I believe I promised to report the result of the tests I designed to the Mechanic. I now make a tardy fulfilment of that promise by expressing my astonishment at finding by visual observation that the stone lay on the 21st of December last eight degrees too far S. of the exact line. I am unwilling to believe that the stone has been moved since it fell. If we suppose the stone to have originally indicated the point of lowest sunrise, that is ten days later than the 21st of December, will "F.R.A.S." kindly tell me how much of these eight degrees might be subtracted? Also, to account for the remaining differences: whether there is any good reason to think a change has taken place in the inclination of the earth's axis since Neolithic times? I ask the latter question because I see that Mr. Petrie, author of "The Pyramids and Temples of Gizeh," seems to account for the inexact orientation of the Great Pyramid in this way: He shows this pyramid to have been built in the transition period between the bronze age and the iron age of Egypt, which date might well be contemporaneous with our Late Stone age, as the successive waves of civilisation of course would sweep westward but slowly. Can any reader tell how much the Great Pyramid is out of true line?—Neo.

[52815.]—**Sunsets.**—The sunsets and sunrises have lately been very beautiful and surprising. I see some attribute the colours seen, and the blue sun and blue moon, &c., to the effect of dust from volcanoes high up in the air. Ought not the colours of the stars to be affected, and has anything of this kind been observed?—Edwd. Thos. Scott.

[52816.]—**L. & S.W.Ry.**—Will "Meteor," or other loco. correspondent, kindly give dimensions and sketch of the new bogie express engine 454, built by Messrs. R. Stephenson and Co., Newcastle, last year, and oblige?—H. N.

[52817.]—**S.E.Ry.**—Can any other kind correspondent give particulars of single driving engines of 81 class on this line?—H. N.

[52818.]—**Clamp Bricks.**—Will some brother reader of "ours" give me a little information on the manufacture of clamp bricks? I have a piece of land with some clay on it, and I want to know what kind of cinders or ashes is used, and the proper quantity, to be mixed with a cubic yard of clay. Could I make the bricks by machine? are the bricks put close together or open in the clamp, and how is the fire started?—A Four Years' Reader of the "E. M."

[52819.]—**Steam Brake.**—Will Mr. Stretton, or any other engineering reader, give a sketch of "sledge brake" introduced by Mr. McConnell on the North-Western Ry.?—Historian, M.I.M.E.

[52820.]—**Lickey Incline.**—I shall be glad to know the length and gradient of this incline. Also details of an engine specially constructed in America to work it.—Historian, M.I.M.E.

[52821.]—**N.E.R. Bogie Engines.**—Will any correspondent oblige with details of the new North-Eastern bogie engines which are being constructed by the Company, which, it is stated, will run the East Coast expresses?—Historian, M.I.M.E.

[52822.]—**Links in Locomotive History.**—Can any of your readers remember some broad-gauge engines built by Sharp, Stewart, and Co., 1846-7, for working between Bristol and Gloucester? If so, will they oblige with some details, and state if these engines are still at work?—Historian, M.I.M.E.

[52823.]—**Electric Lamp.**—Will "Sigma," or other kind reader, say what form of electric lamp and battery would be most suitable to use in a small laboratory to notice the gradations of colour in volumetric analysis?—Gas-Lamp.

[52824.]—**Curing Albatross Skins.**—Will some correspondent please inform me how to cure and clean a couple of albatross breasts? They smell very fishy—having been in their raw state for some months.—S. G. Bryant.

[52825.]—**Regulating and Dividing Current.**—A dynamo is driven by a steam-engine at an even rate, and gives a current equal to 40 Bunsen cells. In what manner can the current be best regulated and subdivided in the laboratory to give one or other cell power without altering the speed of the engine? Can it be done by interposing resistances? And if so, what approximately would be required to absorb the power of one cell?—Lecturer's Assistant.

[52826.]—**Cleaning Binding Screws of Bunsen Batteries.**—Will some one kindly suggest means of cleaning binding screws of Bunsen batteries? The holes and inside parts of the clamps get very foul, and with a large battery cause a great deal of bother to a—Lecturer's Assistant.

[52827.]—**Ramsbottom's Scoop for Locomotives.**—To Mr. G. Pinnington.—I presume that by g is meant the velocity which a body would acquire in one second due to the action of gravity = 32. Suppose that the velocity of the engine in feet per second to be 60; then $\frac{60^2}{32 \times 2} = S = \frac{3600}{64} = 56{\cdot}25$ft. Please say whether I am correct?—Feed-pump.

[52828.]—**Bad Throat.**—Would any of our medical readers be kind enough to say what would be good for my throat? I have been under one doctor, and he said it was relaxation of the uvula, and gave me a blister, and something to paint the inside of my throat; but it did not answer. Another doctor cauterised the papilla of my tongue, gave me a medicine that caused me to feel sickly, and to gargle with alum-water; but it does not do. Symptoms: A tickling sensation in my throat which causes me to cough; but there is no phlegm or saliva with the cough. If I walk uphill quickly I feel very short of wind, and the cough is very troublesome. Same if I exert myself with physical labour. Yet when I am at rest I feel all right.—Harry Bhill.

[52829.]—**Manchester v. London Expresses**—I trust your readers will not let this most important discussion drop out of sight. The G.N. and M.S. and L. Ry. Companies have the longest route, yet have "determined to run in as short time as the others, no matter how much the others reduce." This is war to the knife, and is bringing up the single and coupled engine question again. The L. & N.W. Co. propose to reduce the weight of trains, and put the Lady of the Lake class of engines to run them. It therefore only remains to be seen what the Midland will do to regain its Manchester traffic. I shall be glad to hear Mr. Grey's views on single or coupled engines for working such special service expresses.—Historian, M.I.M.E.

[52830.]—**Coal-burning Locomotives on M.Ry.**—Relating to the testimonials to Mr. Speight, a correspondence has taken place in the *Times* with regard to improvements introduced on the Midland Railway. One claim is that Mr. C. Markham was the first to design coal-burning locomotives on the Mid. Ry. Now, with all due respect to the "leading journal," I doubt the fact. During Dec. 1857 and Jan. 1858 I well remember seeing two goods locomotives under construction at Messrs. Beyer, Peacock, and Co.'s works in this city. These two engines were to burn coal on the Mid. Ry., and, in fact, did burn coal on that line before the Markham system was perfected in 1859–60. From the moment the two engines in question left Messrs. Peacock's works, I have neither heard nor seen them. Would any kind readers oblige me with their numbers, and any details of their working?—Historian, M.I.M.E., Manchester.

[52831.]—**Reagent.**—Will Mr. Allen, or other of our chemical readers, give the most delicate reagent to use for neutralising an acid liquor? I have tried phenolpthalein and dimethaniline orange, and have had to go back on freshly-prepared "litmus solution," as I find the two above-named reagents are not nearly so delicate as "litmus."—Brine.

[52832.]—**Legal.**—To Mr. Wetherfield.—I hold a place in Ireland on lease assigned by previous tenant. Previous tenant owed Income-tax (sched. A) for two years previously. I refused to pay for the one year when the old tenant was entirely in possession; but paid for second year, when I held for part time, and for the last three years. Collector has acknowledged receipt of the money each time; but refuses to hand me the proper receipts until the year's tax owing is paid. Can he legally do this?—E. Hall, Little Island, Cork.

[52833.]—**Water Heater.**—I have an engine 12h.p. (non-condensing) and a boiler 20h.p. Would any legal friend express opinion what sort of heater would suit best for heating the feed-water by exhaust steam from the engine, but not to mix the steam with the water? Would it keep any deposit out of the boiler? I should like it so that I could clean it out. We use much more steam, independent of the engine.—W.

[52834.]—**Damp Schoolroom.**—Can any reader of "ours" suggest a remedy? It is of iron outside, then felt, then matchboarded. Ridge roof, with ventilators always open. Zinc tubes from floor rising about 5ft. around sides. Slight current only circulates through these. Brick foundation on fairly dry soil. Being a Sunday-school, it is not open much. Windows open on top only. Which is best—windows and ventilators always open, or room kept closed up?—A. E. B.

[52835.]—**Calculation of Cometary Orbits.**—Arago, in his "Popular Astronomy," says that if you have three good observations in Right Ascension and Declination you can, by means of a simple calculation, determine the elements of the comet. To effect this, he says, you have to take the six elements of a planet's orbit (inclination, semimajor axis, eccentricity, longitude of perihelion, longitude of ascending node, the longitude of the position of the planet at a given epoch), from which you get two equations. You then take three observations in Declination and Right Ascension, and insert them in the two above-mentioned equations. You can get six equations, which give the six elements of the new body. Would any astronomical reader explain the above method? Also give me a list of the elements of the comets which have appeared from 1874 to present date.—C. E. Tweedale.

[52836.]—**Daniell Cells.**—I have a number of the above cells, which cause me a deal of trouble. The solution in porous pot becomes charged with sulphate of copper, which if precipitated on zinc, causes the evolution of the current to be intermittent. Are the porous cells too porous, or is it from the unavoidable osmosis? The solutions are nearly the same density, as I use solution of chloride of sodium for porous cell.—Perplexed.

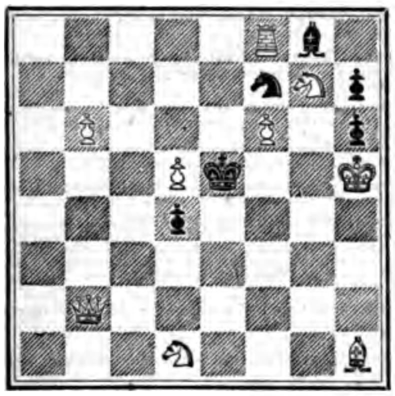
[52837.]—**Storage Battery.**—Will any correspondent of this journal kindly give directions to make a storage battery to drive a Trouvé motor, the armature of which is 8in. long by 4in. diam.? A sketch would oblige.—W. T. Smith, Dunedin, N.Z.

CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Bryn Rhedyn, Llandwrog, Carnarvon.

PROBLEM DCCCLXXI.—By SOPHIE SCHETT.

Black.



White. [9+6

White to play and mate in two moves.

SOLUTION TO 869.

White.	*Black.*
1. Q-Q 8	1. K-K 3 (a)
2. Kt-Kt 4	2. Anything
3. Q mates	
	(a) 1. K takes Kt (b)
2. Q takes P	2. Anything
3. Q or B mates	
	(b) 1. R takes P
2. Q takes P (ch)	2. K moves
3. Q mates	

NOTICES TO CORRESPONDENTS.

CORRECT Solutions to 868 by D. Mackay (eight variations only given), Silvertown (ditto), T. H. Billington; to 869 by R. A. Bennett and F. K. (but all variations must be given).

D. MACKAY.—869 can nearly be done by your method; but there appears no mate if 1. $\frac{}{\text{K-K 3}}$; if 2. $\frac{\text{Kt-Kt 4}}{\text{R takes P}}$.

A. SCHMUCKE.—Your solution will not do; if 1. $\frac{}{\text{K-K 3}}$ 2. $\frac{\text{Kt-K Kt 4}}{\text{R takes P}}$ 3. Q-K 4 is not mate as Kt can take Q.

"E. M." Correspondence Tourney Game between Messrs. Vincent (*White*) and Blake (*Black*):—

(Ruy Lopes.)

P-R 5, R-K 3 (o) / 33. R-B 8 (ch), K-R 2 / 34. R-B 7, R takes Q B P / 35. B-B 4, R takes K Kt P (ch) / 36. R takes R, B takes R / 37. K takes B (p), P-B 4 / 38. R takes B P, P-R 3 / 39. K-B 3, R-K 8 / 40. R takes B P, R-K B 8 (ch) / 41. K-K 3, P-Kt 4 / 42. P takes P *en pass.* (ch), K takes P / 43. R takes P, R-K 8 (ch) / 44. K-Q 4, R-Q 8 (ch) / 45. K-B 4, R-K B 8 / 46. R-Q 6, Resigns.

NOTES.

(a) The usual move here is R-K sq.

(b) Although this move (Winawer's) tends for the moment to retard Black's game, we prefer the book move, B-K 3.

(c) Black's game is cramped B-R 3 is not so good as the text move, however, as the attack must be on the K side.

(d) If P-Q 3, White wins by 13. Kt takes B (ch), &c.

(e) If 15. $\frac{\text{R-Q 3}}{\text{K-R sq}}$

(f) White still keeps up his attack.

(g) At last!

(h) A mistake. Q-B 3 is quite safe.

(i) A good rejoinder.

(k) If now Q-B 3, White could still play P-B 5.

(l) So ends Part I. of this game. Forces pretty equal, after all this fighting White at once starts a new attack out of the remains of the old, giving Black throughout the game not a moment's rest.

(m) Inviting; but perhaps P-B 4 would be safer.

(n) Another mistake. He should have played R-K 3; but the bait was tempting.

(o) Could not Black now have ventured R takes B, followed by R takes Q B P?

(p) Black now feels the hook. The result of his 32nd move is the loss of his B, and so of the game.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 23, and unacknowledged elsewhere:—

V. BICHOT.—Geo. Pearson.—Walker and Co.—Barnett and Foster.—Lt.-Col. Hunter.—Selig, Sonnenthal, and Co.—Dr. Mantell.—Rev. A. Willan.—Major Watkin.—H. Milnes.—J. S. Queen and Co.—Albo.-Carbon Light Co.—A. S. L.—J. H.—A Fellow of the Royal Astronomical Society.—Lt.-Col. Ross.—J. S. C.—J. H.—T. A. Wilhelm.—T. Richards and Co.—B. Baugh.—David.—Engine Driver.—W. Routledge.—Old Rug.—D. W. Williams.—P. Ward.—E. D.—Cosmos.—E. E.—J. Isherwood.—R. Hannen.—A. Watkins.—T. Taylor.—Augustus.—Iolanthe.—Chemicus.—Thomas Thompson.—Organic Chemist.

JNO. ATKINSON. (The process is much too long, and can only be carried on with proper plant. It is obtained by the destructive distillation of wood, and is distilled off the crude pyroligneous acid.)—Q. M. S. (How can any one answer such a question without more details? The battery solution is, however, most likely sal-ammoniac.)—APPRENTICE. (Do you mean how much? If so, it depends on how it is laid on. You can easily make the calculation yourself.)—W. J. (We do not know one that can be recommended. There is very little done in your trade there. 2. We are not sure, but think it is by Mr. Abbott.)—T. H. P. (See the queries inserted last week. It is expressly stated to be suitable for lighting—that is as suitable as any practically free from fumes.)—DEMETRIUS. (Inquire of any bookseller. 2. We have not heard of any accident of the kind. 3. There are two handbooks published by Lockwood and Co., but they are intended primarily for apprentices and the trade.)—AVE ET VALE. (Under the circumstances, do you think he would offer an opinion without seeing the patient? Refer to what he said on pp. 310, 478, Vol. XXXV. Glucose is $C_6H_{12}O_6$; sucrose is $C_{12}H_{22}O_{11}$.)—J. H. B. (It might answer if you can keep up the blast; but we should prefer one of Fletcher's furnaces.)—DOT. (No doubt you were answered in this column and referred to p. 21, Vol. XXXII. You can change your name as often as you please; but if you expect property to be left you had better consult a lawyer, who will see that the change is properly enrolled.)—VOLT. (It is impossible to give sketches and ask questions of the kind for every size that our readers may desire to make. You must see what has been said before, and experiment on that.)—ASSISTANCE. (There is only one way of setting the ordinary pattern. All you have to do is make the flue in a spiral.)—THOS. BOOT. (Magnesium wire or tape. It is a metal. Watch replies 52620.)—E. S. (Doubtful if there is anything that will do what you want.)—MARLOW. (The Léclanché—see indices.)—J. GREEN. (We have given hundreds—see the indices. The cheapest is made with logwood and sulphate of iron.)—PHOTO. (You have not made it soft enough. Properly made, it would lift 40lb. with adequate battery power.)—YOUNG STUDENT. (You will find something about it in back volumes; but not much can be done.)—ELECTRIC BELL. (A knowledge of electricity. Any of the usual text-books. See previous replies.)—C. K. (You will get an idea from p. 256, Vol. XXX., or better on p. 493, Vol. XXVII. The cure for neuralgia is given on the authority of an American physician. We should think the direct application of the current the simplest and best plan.)—W. H. ANGIER. (The Westinghouse coupling was illustrated on p. 196, Vol. XXXV. 2. We do not know where to find the list of temperatures required.)—R. E. (You will find a great deal about Psycho in Vols. XXV. to XXVII. The explanation generally received is a concealed human being.)—J. W. GREEN. (Have you any idea of the plant you would require to make an incandescent lamp that you can buy for a few shillings? See recent numbers as to the battery power required—p. 437, last week, for instance.)—J. R. JACK, LARGS. (See p. 426, Vol. XXXVI., and the indices of the last three volumes. The glass need not be thick. It can be cut to a circle with a diamond, and the centre hole should be round. You do not appear to be aware that the question has been recently fully discussed.)—HEAT. (Use the tables already calculated, such as can be found in Molesworth's Pocket-Book. 50lb. steam (atmosphere included) has a temperature of 281° Fahr. You confuse units of heat with degrees of temperature.)—BENDIGO. (Nominal horse-power is utterly useless. 2. It depends entirely on the pressure of the steam and the speed of working. A cylinder 2in. stroke by 1in. diameter would drive most of them with a pressure of 40lb. of steam.)—WM. JAMES. (Yes, they will do, but special forms are advisable, as the heat concentrated on the slides rapidly destroys the latter.)—A READER. (What you have used produces a stain, whereas you apparently want a japan. See the indices for several recipes.)—ENRIQUE. (They are made of glue and treacle, about 1lb. of best glue to 4lb. of treacle. Dissolve the glue after soaking, add the treacle; boil for a couple of hours and pour into moulds. Use more glue in hot weather.)—IMPROVER. (There is Buchan's book published by Crosby Lockwood and Co., Stationers' Hall-court, E.C., price 4s. You know the articles in this paper by Mr. Davies, we suppose.)—DORA. (We do not quite understand you. Women can claim their "rights," as a rule, at any time; the difficulty, perhaps, being a previous agreement between the sexes as to what those "rights" are. If you mean, Can you receive the interest of money left to you before you are 21?—that depends, we suppose, on the terms of the trust created by the person who left you the money. What does the will say?)—A. H. K. (The *Times*; at intervals during January.)—LAMB. (At that time of the evening, this time of the year, you ought to have had a light; still, if the other facts are as you say, we should advise you to consult a solicitor with a view to claiming compensation from the driver who ran into you.)—RAMCHULLUNDER. (If the solicitor does not receive costs from the debtor, his own client is, of course, liable—is that what you mean?)—AMOS. (None that we know of.)—J. S. C. (We cannot ask correspondents to enumerate the requisites for successful inventions. The only qualification for notice in these pages is merit or novelty.)—T. J. O'C. (Our space does not permit, except in very exceptional cases, of the reproduction of problems from books.)—ZERO. (Consult a respectable solicitor, and tell him all you have told us. The cost will be trifling, and you will get the thing done at once. If you begin to consider the different opinions you would get in reply to your query in these columns, you will never do anything at all. No man who has any proper regard for his wife and family ought to rest easy until he has made a proper will.)—J. B. P. (1. All depends on the evidence. If by any negligence you contributed to the lady's accident, you will certainly have to compensate her; on the other hand, if you did all you could to prevent it, and paid her doctor's bill afterwards, and the lady got about again in a few days, we should advise you to consult a solicitor with a view of defending any action that may be taken against you. Other query shall appear next week.)—J. S. B. (Use vulcanite or porcelain. The solutions cannot be kept too clean. Lead would certainly be acted upon.)—JEWELLER. (See the index of the last volume under Hands, perspiring.)—BENJ. TETLOW. (There is no work on the practical part of the subject; but information can be found in such books as Percy's "Metallurgy of Iron and Steel." Mixing and other details would depend too much on the character of the ores to be mentioned in a book, except in a general way.)—FRANCIS. (Any of the elementary textbooks would do; but perhaps Sir E. Beckett's "Astronomy Without Mathematics" (Society for Promoting Christian Knowledge) would be the best for your purpose.)—G. R. CARNAC. (The questions have been all answered so far as is possible in back numbers, and that recently. You will want 10 or 12 cells; double carbons, if you like; but see p. 379. Which new primary do you mean? We have described all, we believe. We cannot say, but it might be, if the lamp is of only one or two candle-power.)—A POACHER IN EMBRYO. (Surely, if the information is worth having, it is worth the cost of a number. For barrel-staining see p. 86, Vol. XXXV. 2. The Acts relating to the Preservation of Game can be bought at the Queen's Printers, East Harding-street, E.C. 3. Boots made of hippopotamus hide are said to be the best; but a pair of stout leather walking-boots, well greased, are good enough for most people.)—WM. M. (You will find one on p. 433, last week's issue. The other queries are of the nature of advertisements.)—AMATEUR. (We were not aware they are coated. There is nothing that will make them resemble meerschaum.)—EXCELSIOR. (We cannot determine which of Siemens' burners you mean; but they have all been described in back numbers. See p. 582, Vol. XXXII.; p. 373, Vol. XXXIII.; p. 588, Vol. XXXV.; also p. 443, Vol. XXXVI.)—W. B. (We do not understand you. Surely you would not turn a jet of steam into a smith's fire.)—ELECTRIC JACK. (There are plenty of instructions for electric bell-making and arranging in back numbers. It is impossible to say what is the matter with yours from the description sent. The wire (36) is rather fine for a magnet; 26 is quite fine enough for the size mentioned, and the finished coil should be about three times the diameter of the core. Read up what has been given, and you will no doubt discover what is wrong.)—H. A. (Perhaps he has the distemper. See the back volumes, p. 506, Vol. XXXVI., and elsewhere.)—LAUNCH. (It is a patent, and consists of a chamber filled with glass balls about the size of beads. See p. 412, Vol. XXXVI. 2. Smear over with a rag moistened with vaseline.)—PERUVIAN. (The only way is to get one and try. The inventor is a well known professor. Are you not mistaken as to the "settled climate"?)—B. BOLT. (It rests entirely with yourself. Follow the advice of the doctor.)—RUSTIC. (Answered many times. If you must have it permanent, grind the glass with flour emery.)—MICROSCOPIST. (You must be recommended by three fellows; pay two guineas entrance-fee, and two guineas annual subscription.)—HYDROGENIUM. (Mere personal opinion is useless; it is scarcely likely that anyone has studied in both.)—VERA SOLIDAQUE. (If leadfoil will not stop it, we know of nothing. You do not say the cause of the dampness.)—ALBERT HALL. (You could try caustic soda, or even a strong solution of washing soda.)—CHEMICUS. (Every one of your seven queries has been recently answered. Please consult the indices.)—ONE WHO SUFFERS. (The only remedy for ingrowing toe-nail is that given by Dr. Edmunds, p. 284, Vol. XXXIV. A piece must be cut out of the centre of the nail, from the front to as far down the quick as can be reached.)—H. R. B. (You will find much information in back volumes, but the calendar gives the actual work required. We believe Mr. H. K. Lewis, 136, Gower-street, W.C., publishes a guide.)—COQUETSIDE. (Known as the blue process, ferroprussiate, &c. See p. 325, last volume, p. 64, Vol. XXXVI., and the indices under any likely heading.)—A REGULAR SUBSCRIBER. (You should have mentioned the page on which previous answer appeared. That was written with your question before us, and was a direct reply. We do not know any reason why you should not learn to play the instrument. As to the other question: paper tubes will do. The expression is definite enough, but it should mean 300 times the size.)

Every Workman connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 31, Tavistock-street, Covent-garden, London, W.C.

"THE BUILDING NEWS" is the Principal Journal, representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. XXIV., XXVII., XXVIII., XXX., XXXI., XXXII., XXXIII., XXXIV., XXXV., XXXVI., and XXXVII., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in March and September, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

Sixteen words	0	6
For every succeeding Eight Words	0	6

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

Epps's Cocoa.—GRATEFUL AND COMFORTING.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.* —Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence.

Holloway's Pills have many competitors, though no equals, for supplying the young and delicate with a simple, strengthening, and purifying aperient. These Pills, composed of the finest balsams, are particularly adapted for all complaints peculiar to females, and are most serviceable at the critical periods of early and mature years.

OUR EXCHANGE COLUMN.

◆◆◆

The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.

◆◆◆

I have 2 Wright's patent **Gas Fires**, new, with fittings and Asbestos complete, cost 30s. each; will exchange for block tin, pewter, and thick bar copper, to 40s.—S., 19, Stafford-street, Sunderland.

I have a quantity of new **Water and Steam Iron** PIPE FITTINGS, useful assortment, from ¼in. to 2in., equal to about £24, list price: will exchange for brass goods.—S., 19, Stafford-street, Sunderland.

Wanted, **Dynamo**; will exchange bicycle, tricycle, or photographic apparatus.—GRIME, Prospect-street, Hull.

Infusorial Earth, four bags, about 3 cwt. Will exchange anything.—DRURY, 51, High-street, Hull.

½-Plate bellows **Photographic Camera**, two lens, double slide, folding stand, burnishing machine, chemicals, printing frames, dishes, several Bicycles and Tricycles. Exchange for jewellery or anything useful.—TAYLOR, 20, Vane-street, Hull.

Wood Turner's Lathe, 7in. centre; Carpenter's bench iron screw; ½ horse-power boiler, welded: exchange.—Apply, by letter, to W. SMITH, Bilston-road, Wolverhampton.

***Steelyards**, by Avery, 14lb. to 18cwt. Capital Desk Top, 3ft. square; exchange.—Apply, by letter, to W. SMITH, Bilston-road, Wolverhampton.*

8ft. **Mahogany Counter**, Gasalier, Bicycle Rims, "Design and Work," Vols. VII., VIII., IX., parts of others; six parts "Mackenzie's Chemistry," 2s. each. "Life of Agnes Home," "Welch Grammar," 4s. 6d. "Bell's Anatomy," pair of skates, 2s. 6d. Silver Albert, Wedding Ring, Lantern and Slides, Dentist's Key, Forceps, 2lb. 36 cotton covered Wire, Medical Coil; exchange anything; want poultry, canaries, tools, optical goods.—6, Bank's Town, Sheerness-on-Sea.

Siemens Armature, 12in. by 6in., with commutator, ½in. spark, coil, and two quart Bunsen batteries, for portable coil and battery in lock-up case.—T. A. C., Fairfield House, Warrington.

Horizontal Engine and Vertical Boiler, cylinder brass, 1¼in. by 3in., boiler copper and iron, 15in. by 7in. Exchange for 3 feet gap bed, or 4in. back gear lathe heads—Address, C. MINTO, Byers-green, Spennymoor.

Three **Batteries**, flat cells, in neat little lock-up polished cabinet, ratchet and brass fittings, value 25s. Want modern 5 by 5 or whole-plate bellows camera, or offers.—CHAPMAN, Coldham Hall, Bury, Suffolk.

Six-Barrel Revolver, in excellent condition. Would exchange for cabinet of well mounted and correctly named entomological objects, or for books on the subject.—J. GREGORY, 24, Old Millgate, Manchester.

"**English Mechanic**," last 17 volumes, unbound, wanted, an offer in exchange; anything useful invited.—R., 1, Canonbury-lane, Islington, N.

Telescope, 4in. brass reflector, 27in. long, metal speculums, brass pillar and tripod stand; exchange for 3in. lathe or offers.—J. W. WALKER, Watchmaker, 55, Renfrew-street, Glasgow.

Telescope Metal Speculums, 4 sets, 4½in. to 1¾in. diameter; exchange micro condensers, prisms, or offers.—J. W. WALKER, Watchmaker, 55, Renfrew-street, Glasgow.

Photograph Lens, by Dallmeyer, cabinet size, portraits, combination; what offers?—McINTOSH, 7, Lancaster-place, Richmond.

Wanted, one of **Booth's Mitre Machines**. Will give in exchange lathe, 5in. centres, 3ft. iron bed, planed bright.—R. KING, Junr., Cowley, Oxon.

Wanted, **Hand Lever Tricycle**, for boy without legs; aged 16; good exchange.—Particulars to G. CLARKE, 15, Bank-terrace, Lindel-in-Furness, Ulverstone.

Silber Brass Lamp, reflector, and chimney, for magic lantern, beautiful large light, nearly new, cost 11s. 6d. useful offers requested.—S. WINDLEY, Charlton, London.

Bicycle or Tricycle wanted. Exchange for Magic Lantern and Slides, by good maker.—Send full particulars to FRED. SPALDING, Junr., Chelmsford.

In exchange, **Liebig's Condenser**, Test Tubes and racks, Bunsen's burner, and other duplicate apparatus, suitable for beginner. What offers?—2, Spring-hill, Kingsdown, Bristol.

Double-barrel **Air Pump**, in splendid condition. Would exchange for folding camera, microscope slides, or what offers?—2, Spring-hill, Kingsdown, Bristol.

Good set **Wood Heads** for lathe, bushed, and mandrel complete. Exchange for screw-plate and taps, model work. —A. C., 51, Worington-gardens, Notting-hill.

Lathe Head, Mandrel, and Hand-Rest, 3 dozen alphabetical types, ¾ letters. Exchange for drill chuck; on approval.—A. C., 51, Worington-gardens, Notting-hill.

Steam Pressure Gauge wanted, not over inch dial; will give nearly new watch, with seconds hand.—R. W. WRIGHT, 125, High-street, Lincoln.

Three-quarter H.-P. **Vertical Boiler**, three-quarter h.-p. and half h.-p. horizontal engines, working order; wanted, one or two man-power gas engine in exchange.—T. CARTER.

Pressure Gauge, by Hayward, Tyler, and Co., 4in. diameter, indicates to 200lb. pressure; wanted, gauge, 1in. diameter, good order.—T. CARTER, 12, Park-street, Stafford.

1876 **Drill Chuck** takes up to ½in., with fitted plug, never been used; exchange Fletcher's foot blower.—R. GILL, High-street, Chorley.

Horizontal Engine, complete, cylinder 2¼ by 4½; for tricycle or dynamo.—117, Cockburn-street, Liverpool.

Exchange Howe **Sewing Machine**, perfect, and Beam Engine, and boiler, new, for Harmonium, strong tone; case no object.—SMITH, Engineer, Tutbury, Staffordshire.

Flywheel, bored and turned, with pulley on side, suit one-horse Engine or Lathe; for Pair strong Lathe Standards.—SMITH, Engineer, Tutbury, Staffordshire.

Lathe (small) wanted, suitable for winding electric bell coils and small brass work. Exchange scientific books.—L., 101, Uxbridge-road, London, W.

Lathe Tools and Drills for brass finishing. Will give exchange "La Semaine Francaise," 1880 to present date (unbound.)—L., 101, Uxbridge-road, London, W.

Steam Gauge, about 4 inches diameter (Calvert) to indicate 5 to 150lb. Wanted in exchange.—Send particulars to WHEELER, Preston.

I have 20 numbers "**Clark's Dictionary of** MECHANICS," 16 of "Amateur Work," a Horizontal Boiler, with brass fittings, riveted. Will give the lot for a good old Bicycle or a Model of anything.—E. P., Railway Inn, Abertillery, Newport, Mon.

Sewing Machine, Wright and Mann's patent Treadle Silent Rapid; good condition. Exchange Organ Accordion, Lever Watch, or offers.—S., 28, Fenton-street, Eckington, Chesterfield.

Wanted, second-hand **Drilling Machine**, complete, in exchange for new Tricycle, cost £14. Send all particulars.—JOHN FULLER, 12, Craven-buildings, Newcastle-street, Strand, London.

Good **Fishing Rod**, quantity flies, books, lines, &c. Exchange for Magic-Lantern and Slides, Camera (Carte), or offers.—Address, H. YEEND, Oakley Cottage, Cemetery-road, Cheltenham.

Patents for Inventions.—Webster's, Agnew's, and other Works wanted: for several years "Punch."—Apply, D. MASON, Patent Agent, 63, West Regent-street, Glasgow.

Good **Vice**, three Scribing Blocks, five different size Callipers, Steel Rule, Squares, &c. Exchange Microscope or Lantern Slides.—67, Thomas-street, Aston-road, Birmingham.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, FEBRUARY 1, 1884.

THE PHYSICAL CONDITIONS OF IRON AND STEEL.

AT the meeting of the Institution of Mechanical Engineers, held last week, Prof. D. E. Hughes, F.R.S., read an important paper on "The Physical Condition of Iron and Steel," which is in some sense a complement to his paper on "The Molecular Rigidity of Tempered Steel," in which he advanced the theory that the molecules of soft iron were comparatively free as regards motion amongst themselves, whilst in hard iron or steel they were extremely rigid in their relative positions. Prof. Hughes has since then widened the field of research so as to embrace all the physical changes which occur in iron and steel, and the results he has obtained are embodied in the paper read last week. The primary object of the research was to discover if possible a method of ascertaining the physical condition of any piece of iron without destroying or changing its existing state; and Prof. Hughes believes he has attained the desired end by the application of certain phenomena of magnetism, which indicate clearly the slightest change in the molecular structure of iron or steel, no matter what may be the condition of those metals, or the size and shape of the pieces operated on. We need not stop to point out that any trustworthy method, which can be readily applied, of ascertaining the temper (using that word in its widest sense) of any given piece of iron or steel will be of the very highest value to engineers and mechanics in all branches; but will at once proceed to give such explanation of the method as is possible in our space, leaving those interested who may desire more detailed information to procure a paper which will be recognised as one of the classics of the machinist's library. It is well known to most of our readers that soft iron takes a higher degree of magnetism, and parts with it more quickly, than steel; also that tempered steel retains magnetism longer than does soft steel. It might be expected, therefore, that by the aid of an instrument which would measure the degrees of magnetism correctly, we should be able to include all varieties of iron and steel between the two extremes of softness (as in annealed iron), and hardness (as in high-tempered steel); but Prof. Hughes soon found that such was not the case when pieces of iron were magnetised to saturation or even partially so. However, by employing extremely feeble magnetising powers, such as the current from one Daniell cell reduced as found best for the dimensions of the iron, by passing it through resistance coils varying from 10 to 100 ohms, Prof. Hughes found that the following laws hold good with every variety of iron and steel: 1. The magnetic capacity is directly proportional to the softness or molecular freedom. 2. The resistance to a feeble external magnetising force is directly as the hardness, or molecular rigidity. With sixty different varieties of iron and steel Prof. Hughes has found that each has its fixed points, beyond which annealing cannot soften, nor tempering harden; consequently, if all varieties were equally and perfectly annealed, each would have its own magnetic capacity or its specific degree of value, by means of which its place and value could be at once determined. If a single specimen of, say, hard-drawn iron wire is taken, and its magnetic capacity noted, it is found that the value rises after each partial annealing, until an ultimate softness is obtained, which is the limit of its molecular freedom. Thus we can study the best methods of annealing, and find at once the degree of softness in any given specimen. Similarly, in the case of tempering, we may reach the ultimate molecular rigidity, and determine the state of any given piece. In soft Swedish iron Prof. Hughes finds that tempering hardens only 25 per cent. on the scale adopted, while mechanical compression, such as hammering, hardens 50 per cent. In cast steel, on the other hand, tempering hardens it 400 per cent., while mechanical compression hardens not more than 50 per cent. Between cast steel and Swedish iron there is a long series of steels and irons varying in hardness and softness between the two extremes. Prof. Hughes's theory of molecular freedom (as in soft iron) and molecular rigidity (as in cast steel) fully explains all the changes we are enabled to perceive and measure; but the theory is not necessary to understand the results attained by the aid of the instrument which Prof. Hughes has called the magnetic balance. This consists of a delicate magnetic needle 2in. long, suspended by a silk fibre so that its pointer rests near a fine black line indicating zero. The movement of the needle is limited by ivory stops to two-tenths of an inch on either side of zero. When the north end of the needle and its zero index are north, the needle rests parallel with its index; but the slightest external influence, such as a piece of iron a millimetre in diameter, placed at 4in. distance, deflects the needle to the right or left, according to the polarity of its magnetism, and with force proportionate to its magnetic power. If on the other side of the needle an exactly similar piece of iron is placed [illegible] the same distance, the needle returns to zero, because the two pieces of iron balance each other; and if we know the magnetic value required to balance the first piece, we know the magnetic value of both. The iron is placed at a fixed distance, say 4in., resting against a brass stop; its centre should be in line with the centre of the needle, and it should be placed at right angles to the needle, lying horizontally east and west, so as to be free from the directing influence of the earth's magnetism. On the opposite side of the needle at a distance of 12in., is the compensator, a powerful steel bar magnet (3cm. wide, 1cm. thick, and 6cm. long), which turns upon its axis, and carries a pointer to indicate the degree of displacement on the graduated circle. Generally, this bar-magnet is parallel with the needle, the pointer of the compensator and the needle being at zero; but when it is desired to measure the amount of magnetism in a piece of iron, the bar-magnet is made to pass through an angular displacement which balances the magnetic force in the piece of iron, and the index readings on the graduated circle are taken as the comparative values. In order to magnetise the piece of iron by means of an electrical current, a coil of insulated copper wire is placed near the needle, the iron then becoming the core of an electro-magnet. As this coil, independently of the iron, acts upon the needle, it must be balanced by another coil on the opposite side of the needle. The position and power of these coils is adjusted by a lever which enables the operator to find a position where the coils completely neutralise each other. Then a piece of iron being introduced into either coil, the balance is destroyed, and the magnetic influence of the iron core can be measured by means of the rotating compensator or bar magnet. A reversing key is used to change the direction of the current so as to observe any difference in the north and south polarity of the iron core. One Daniell cell is sufficient; but great care must be taken that its E.M.F. is a constant; otherwise its variations would be read as variations in the quality of the iron itself. In addition, a series of resistance coils from 10 to 100 ohms are required to reduce the current sufficiently to bring the whole series from soft Swedish iron to cast steel into range. When it is required to measure the magnetic capacity of pieces of metal varying very widely in dimensions, a series of coils will be needed; but the smallest may have a core opening of one centimetre (0·4in.), which will test rods just a shade smaller down to the finest needle. Great care and considerable practice is needed so as to insure that the iron is placed in a neutral field; but when the requisite conditions are once attained, several readings can be made in a few minutes. There are modifications in the manner of observing, such as magnetising all pieces to the same degree, and noting the amount of current required; but the method described will probably be found most useful.

By means of the magnetic balance Prof. Hughes has determined that annealing not only renders iron soft, but entirely frees it from all strains previously introduced by drawing or hammering. Thus, a bar of iron drawn or hammered has a peculiar structure which gives greater mechanical strength in one direction than in another; but if thoroughly annealed at high temperatures, it becomes homogeneous in all directions, and loses all traces of previous strains, provided there has been no actual mechanical separation into a distinct series of fibres. An instance of the influence of annealing on Swedish iron will be seen in the following:—Wire hard drawn gave 230° of softness as indicated on the balance; annealed at black heat, 255°; at dull red, 329°; at bright red, 438°; at bright yellow, 507°; at yellow white, 525°, which may be taken as its ultimate degree of softness, the maximum being obtained by annealing at a temperature just below that of fusion. Some difficulty was experienced in annealing all wires to the same standard, for steel wires rapidly lose carbon, while pure iron absorbs it. Prof. Hughes therefore made a tube white hot or otherwise, according to the temperature required; the wires were then quickly introduced, and withdrawn the moment they reached the same temperature, when they were allowed to cool in the air. The results of his researches may be thus formulated: 1. The greatest degree of softness is obtained by a rapid heating to the highest temperature below fusion, followed by cooling in a medium incapable of changing the chemical composition of the metal. 2. The time required for cooling varies directly as the amount of carbon in the alloy. In absolutely pure iron rapid cooling does not harden, whilst steel might require several hours or days, even for pieces one millimetre in diameter. Slow cooling has no injurious effect upon iron when cooled in a neutral field; consequently, slow cooling may be adopted in every case where time is no object. Care must be taken that the piece of annealed iron to be tested is not bent, hammered, filed, &c., for the hardening effect of a bend is most remarkable, and the mere cleaning of the surface with glass or emery paper hardens it by several degrees of the magnetic balance scale. The effect of annealing on several samples may be understood from the following:—Swedish iron had its magnetic capacity increased from 230 to 525; puddled iron from 212 to 340; Bessemer steel (soft) from 150 to 291; Bessemer steel (hard) from 115 to 172; crucible fine cast steel from 50 to 84. It follows that for making cores of electro-magnets, Swedish iron is the best that can be used, and the magnetic balance will, no doubt, be used in testing whether the annealing process has been carried as far as it possibly can be. In the case of tempering, that is, increasing molecular rigidity and the power of retaining magnetism, the following figures may be useful:—Crucible fine cast steel tempered at a bright yellow, cooled completely in cold water, had a magnetic capacity of 28; bright yellow, cooled completely in oil, 51; bright yellow, let down in water to white, 38; red heat cooled completely in water, 66; red heat cooled in oil, 72; and annealed, 84. The experiments carried out by Prof. Hughes show that just as there is no means of finding a distinct line between iron and steel by mechanical and chemical tests, so the physical method fails, for ordinary iron is physically a soft steel, and steel is a hard iron. All the series are hardened by tempering; all are hardened by mechanical compression, or by strains and stresses. At the extreme end of the series, towards pure iron, mechanical hardening has a greater effect than tempering; at the steel end tempering has a greater effect than mechanical compression. Prof. Hughes adopts the scale reading of 400° as the dividing line. All specimens that after annealing give a higher reading than that are classed as iron; if below, as mild or hard steel, according to their magnetic capacity. The molecular rigidity gives at once decreased magnetic capacity and increased electrical resistance, which agrees with hypothesis; and from some experiments made with a view of comparing tensile strength with magnetic capacity, Prof. Hughes thinks it will be some day possible to deduce not only electrical conductivity from magnetic capacity, but also tensile strength. We have said enough to prove that the magnetic balance is a valuable instrument, and it only remains to state that its use is free to all, as Prof. Hughes has not protected it by letters patent.

ASTRONOMICAL NOTES FOR FEBRUARY, 1884.

Ec Eclipse; Oc Occultation; Tr Transit of Satellite; Sh Transit of Shadow; D Disappearance, R Reappearance; I Ingress; E Egress. The printing of a phenomenon in *italics* indicates that its visibility is rendered doubtful, either by the brightness of the twilight or by Jupiter's proximity to the horizon.

Jupiter

Is still visible all night long, and continues to be the most brilliant and conspicuous object in the sky; the diminution of his angular diameter from 42·7″ on February 1st to 40·5″ by the 29th being quite imperceptible, save by refined measurement. He is, in every respect, admirably placed for the observer.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	8 0·2	21 10·5	11 13·9 p.m.
6	7 57·6	21 18·1	10 51·7 ,,
11	7 55·3	21 25·1	10 29·7 ,,
16	7 53·1	21 31·3	10 7·8 ,,
21	7 51·2	21 36·6	9 46·3 ,,
26	7 49·5	21 41·1	9 25·0 ,,

So that Jupiter, like Mars, is travelling backwards in Cancer; the path of Jupiter, however, commencing at a point just South of the 6·5th mag. Star μ² Cancri, and extending into the perfectly barren region between Cancer and Gemini.

Mercury

Is a morning Star during the entire Month, attaining his Greatest Elongation West of the Sun (26° 12′) at 5 a.m. on the 14th. His diameter decreases from 8·8″ on the 1st to 5·6″ by the 29th. He is but poorly placed for the observer.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	19 30·0	19 5·7	10 45·8 a.m.
6	19 36·4	19 48·3	10 32·5 ,,
11	19 51·9	20 6·7	10 25·3 ,,
16	20 13·4	19 56·4	10 30·0 ,,
21	20 38·6	19 15·0	10 35·5 ,,
26	21 6·2	18 1·4	10 43·4 ,,

Hence Mercury will be seen to travel from

Sagittarius into Capricornus; but through a region of the sky destitute of any conspicuous stars.

Venus

Is an Evening Star all through February, and her position in the sky is improving as far as the observer is concerned. Her diameter increases slowly from 12·5″ on February 1st to 14·2″ by the 29th, and she is markedly gibbous.

Day of Month.	Right Ascension.	Declination.	Souths.
	h. m.	° ′	h. m.
1	23 3·8	7 26·0 S.	2 18·9 p.m.
6	23 26·2	4 53·1 ,,	2 21·6 ,,
11	23 48·3	2 17·2 ,,	2 24·1 ,,
16	0 10·2	0 20·3 N.	2 26·3 ,,
21	0 32·0	2 57·7 ,,	2 28·3 ,,
26	0 53·8	5 33·8 ,,	2 30·4 ,,

The path indicated by the above Ephemeris carries Venus from Aquarius through the blankest part of the Constellation Pisces.

Mars

Comes into Opposition to the Sun at 11 a.m. on February 1st. He is now visible all night long, and is as favourably placed for the Observer, as he will be for some considerable time. His disc subtends an angle of 16·6″ during the early part of the Month; but this diminishes to 14·5″ by the 29th. The reader must not expect the planet to present the same splendid appearance that he did during the memorable Opposition of 1877 (when his angular diameter was 29·4″); but he is still a very striking and interesting object in the telescope: the Polar Snow and the (supposed) "seas" which diversify his face being well seen with adequate optical power.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	9 2·8	21 36·1	12 16·3 p.m.
6	8 54·6	22 8·4	11 48·5 ,,
11	8 46·9	22 35·1	11 21·2 ,,
16	8 39·9	22 55·6	10 54·5 ,,
21	8 33·8	23 9·6	10 28·8 ,,
26	8 29·0	23 17·1	10 4·3 ,,

Thus Mars will start from a point in Cancer something like 1° South of the 5th Mag. Star ξ in that Constellation—through which he is travelling backwards. On the night of the 19th he will be a little more than 1½° North of γ Cancri.

Saturn

Is an Evening Star; but Southing as he does about 7h. 20m. p.m. on the 1st, and about half-past 5 o'clock at the end of February, is, of course, best seen during the earlier hours of the night. His diameter decreases imperceptibly from 17·2″ at the beginning to 16·4″ by the end of the Month. Little or no change is perceptible in the opening of his rings, and he still presents a beautiful and interesting spectacle to the young observer.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	4 6·1	19 2·6	7 20·5 p.m.
6	4 6·1	19 4·0	7 0·8 ,,
11	4 6·3	19 5·9	6 41·4 ,,
16	4 6·7	19 8·4	6 22·1 ,,
21	4 7·3	19 11·3	6 3·0 ,,
26	4 8·1	19 14·7	5 44·2 ,,

Hence Saturn, as seen with the naked eye, will remain sensibly stationary a little to the West of the 4·3 mag. Star ε Tauri—the Northernmost one in the Hyades.

Uranus

Rises just before 9 o'clock on February 1st, and, approximately, two hours sooner by the last day of the Month; so that he is now fairly visible by midnight. He presents a sensibly constant angular diameter of 4″, and exhibits a very apparent pale blue disc in the telescope.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	11 53·0	1 36·6	3 10·1 a.m.
6	11 52·5	1 40·1	2 49·9 ,,

16	11 51·4	1 48·0	2 9·4 ,,
21	11 50·7	1 52·5	1 49·0 ,,
26	11 50·0	1 57·2	1 28·7 ,,

The short retrograde arc indicated by the above Ephemeris lies, roughly, about half-way between β and η Virginis.

Neptune

Is an Evening Star; but should be looked for during the beginning of the Night, as he is approaching the West, and by the End of the Month sets at Midnight. He is in quadrature with the Sun at 2 p.m. on the 7th.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	3 5·3	15 35·3	6 19·8 p.m.
6	3 5·4	15 35·9	6 0·2 ,,
11	3 5·5	15 36·8	5 40·7 ,,
16	3 5·7	15 37·9	5 21·2 ,,
21	3 5·9	15 39·2	5 1·8 ,,
26	3 6·2	15 40·7	4 42·5 ,,

This very short arc is described in that perfectly blank region of the sky between 3° and 4° South of δ Arietis.

Shooting Stars

Are not common in February. The nights of the 10th and the 19th are those upon which their apparition is most probably to be expected.

Greenwich Mean Time of Southing of Sixteen of the Principal Fixed Stars on the Night of February 1st, 1884.

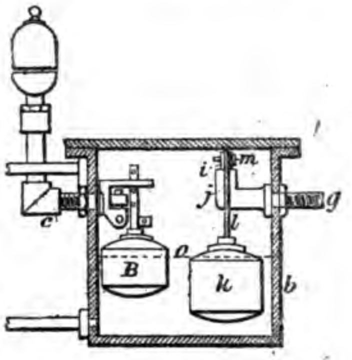
The Method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in February, as also that of determining the Mean instant of its Transit at any other Station, will be found on p. 359 and 360 respectively.

SELF-ACTING BOILER FEED AND ALARM.

The annexed engraving represents a method of regulating the feed to steam boilers by a self-acting apparatus, recently patented by Mr. W. White, of Mansford-street, Hackney. As will be understood, the arrangement can be carried out in a variety of ways, and that illustrated combines in the same apparatus a self-acting low-water alarm in the shape of a whistle. The invention has for its object the regulation of the feed or supply of water into steam boilers by a self-regulating apparatus, so as always to keep the water in the boiler at one level so long as the injection pump acts, and thus make it impossible for a boiler to explode for want of water; and, further, as a safeguard against the pump failing to act, a whistle alarm is attached to a cylinder or other suitable chamber, at the lower part of which is an inlet to receive water from the boiler, and at the upper part of the chamber are an inlet and an outlet (*g*) for steam, by means of which steam is led into the pump or suction pipe. The pipe projects inside the chamber, and to the end of it is fixed a suitable valve and valve box, and in the lower part of the chamber is a float that will rise and fall as the water ebbs and flows. By means of two side rods and a cross bar the float is connected with the valve in the valve box, so that the valve will rise up and lower down with the float as the water ebbs and flows in the chamber and boiler, the effect of which is as soon as the water is pumped into the chamber to the right level the float will open the valve and allow steam to pass through the chamber and pipe *g* into the pump or suction pipe, and prevent the pump from throwing any more water until the valve is again closed, and by this means neither can too much water be got into the boilers nor will the water be allowed to fall below its proper level, it being perfectly self-acting, without the interference of any workman. And, further, in the event of the pump ceasing to act, for the purpose of giving an alarm, a whistle placed either on the boiler or on the chamber is worked by a valve and float, which acts in the same manner as the apparatus for regulating the feed.



In the illustration, a separate float B is shown as actuating the steam whistle, steam being admitted by the pipe *c*; *k* is a float connected by a bow, *l*, to a valve, *i*, working in a box, *j*; the head of the bow being secured to the valve by the pin *m*; *o* shows the water line, and *b* is the chamber or cylinder in which the apparatus is arranged. In the position shown the upper part of the cylinder is filled with steam, the chamber having open communication with the boiler, and all other outlets closed. If, now, the feed pump throws more water than is required, the level will rise and lift up the float *k*, which, in turn, will open the valve *i*, through which steam will rush to the pump through pipe *g* and stop its working. Similarly, if the water falls below the normal level, either in consequence of the pump stopping or failing to throw sufficient water, the float *b* will fall, and allow steam to pass through pipe *e* to the whistle, thus calling the attention of those in charge of the boiler.

PROTECTING COATING FOR IRON AND STEEL.

A method of giving articles of iron and steel a protecting coat of rust has been patented in this country on behalf of Mr. E. Nicolaus, of Lauchammer, Saxony. According to the patentee the new or improved process combines the covering power of oil paint with the fineness of a galvanic covering and possesses an extraordinary durability. The objects are thereby altered chemically at their surfaces only, and there is thus in reality no separate coating. The process can be applied with equal safety to cast iron, wrought iron, or steel. The objects to be patinaed are first carefully ground and polished in order to produce a clean metallic surface, to remove dirt, and to prepare it to receive the lustre or brilliancy required in some cases for the complete effect; then follows the most important manipulation—namely, the annealing of the objects. Cast iron, especially such as is very thin, for artistic and architectural purposes, by reason of its unequal thickness cannot be subjected to the process unless annealed. The annealing of the cast objects is intended to make the material homogeneous, whereby the success of the succeeding operations is secured. So-called tempered cast articles must likewise be subjected to the annealing process: larger objects, such as statues or monumental castings, can be subjected to the succeeding operations without further preparation, as their material possesses sufficient homogeneity. When the articles are regularly annealed they are allowed to cool slowly, and are then placed in a pickle to remove the annealing scale. This pickle may consist of a weak solution of sulphuric or muriatic acid in which the article is immersed for a few minutes: then follows a mechanical working of the surface by scouring in order to remove the scale completely. When the object is completely cleansed, so that all uneven parts and annealing scales are removed, the peculiar patinaing process can be commenced. This process consists in so laying on a dilute inorganic acid (about one part of acid to five parts of water) that the surface is covered with a very thin coating of the liquid. After covering over with this rust-water the object is allowed to dry completely, and it is then brushed or rubbed with clean rags, after which the rusting process is repeated in the same manner as before, and the remainder of the rust which is not fixed is removed after the subsequent drying by means of brushes and rags.

Finally, the previously warmed cast article is painted over with linseed oil, it is then dried in an oven or drying room, and is then covered with colourless lacquer (*spiritus lac*), which can be made highly brilliant at any required parts by wax polishing. Castings treated in this manner become of a beautiful durable black colour when submitted to the action of heat in a stove. For browning wrought iron and steel the above described process gives better results than the ordinary process, and has the advantage of greater simplicity. In treating wrought iron and steel the annealing process is dispensed with, because those materials already possess the homogeneity requisite for the patinaing process.

ON A NEW CAMERA LUCIDA.*

By Dr. Hugo Schröder.

In the recent volumes of the *Journal* of this Society I have met with descriptions and figures of several forms of camera lucida which were new to me. I obtained an example of each, and made a series of trials in comparison with the older forms with which I was already familiar. In all of them I found more or less defects, such as limitation of field, distortion, indistinctness of image or of drawing-point, awkwardness of position, &c. Being engaged later in endeavouring to simplify and perfect the construction and adjustment of Mr. Wenham's high-power binocular prism, I was much interested by the ingenuity of this device, and it occurred to me that that arrangement of prisms might be modified, so as to be available as a camera lucida in which the defects of the forms hitherto made would be considerably reduced if not entirely eliminated.

Assuming a 45° inclination of the microscope to be the position most generally convenient for drawing, I (in June last) drew on a large scale the system of prisms which appeared to be suitable for a camera lucida. Messrs. Ross undertook to construct the prisms to my drawings, and the apparatus was found upon trial to answer my expectations fully. I am induced to describe it here because it has also met with much approbation from microscopists, who were previously disinclined to believe in the possibility of any new device at the present day, which should be substantially better than the numerous older forms which apparently exhausted the subject.

It is well known that all forms of reflecting prisms acting by means of *one* reflection are extremely sensitive in regard to the position of the mirror in relation to the microscope, as also in a less degree in relation to the eye: the slightest deviation from the normal position in many cases entirely destroying the effectiveness of the apparatus. For this reason cameræ lucidæ acting by *one* reflection have not found favour, though their apparent simplicity has induced the construction of many such forms.

In order to obviate the difficulties incident to the use of *one* reflection, many devices have been made acting by *two* reflections, and where these have been so contrived as to act like parallel mirrors, the reflected image has *possessed* the advantage peculiar to this principle, of being practically insensitive to slight differences of position relative to the microscope or to the eye, remaining in fact stationary within a considerable range of adjustment, as in Wollaston's camera lucida.

FIG. 1.

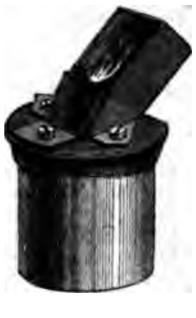


FIG. 2.

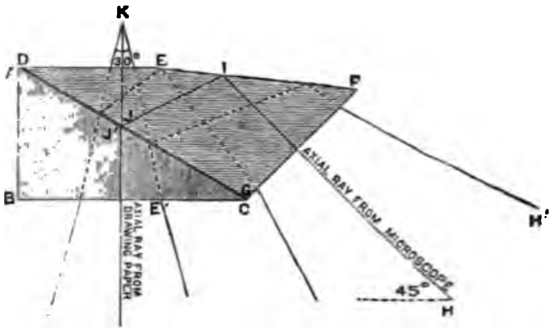


My device (Fig. 1) consists of a combination of a right-angled prism (Fig. 2), A B C, and a rhomboidal prism D E F G, so arranged that when adjusted very nearly in contact (i.e. separated by only a thin stratum of air) the faces B C and D E are parallel, and consequently between D E and B E' they act together as a thick parallel plate of glass through which the drawing-paper is viewed. The rhomboidal prism is so constructed that when the face G F is applied at right angles to the optic axis of the microscope, the axial ray H passes without refraction to I on the internal face E F, whence it is *totally* reflected to J in the face D G. At J a part of the ray is reflected to the eye by *ordinary* reflection in the direction J K, and a part transmitted to J' on the face A C of the right-angled prism. Of the latter a portion is also reflected to K by ordinary reflection at J'. The hypothenuse face A C is cut at such an angle that the reflection from J' coincides with that from J at the eye-point K, thus utilising the secondary reflection to strengthen the luminousness of the image. The angle at G is arranged so that the extreme marginal ray H' from the field of the B eyepiece strikes upon D G at a point just beyond the angle of total reflection, the diffraction-bands at the limiting angle being faintly discernible at this edge of the field. This angle gives the greatest amount of light by *ordinary* reflection short of *total* reflection.

By this arrangement the Ramsden circle over the eyepiece comes just above the camera lucida, and the field of view is not in any way reduced; all that can be seen directly through the B eyepiece (say 30° of field) is perfectly depicted in the camera lucida, whilst the drawing being viewed direct is of course not cut down in field.

In practice the microscope should be inclined about 45°, and the image accurately focused through the eyepiece as usual. The camera is then slid on the eyepiece and pushed down more or less until the microscopical image is seen distinctly and the illumination of the field is equal throughout. The drawing-paper is placed on the table immediately under the camera. The observer will then see the microscopical image projected on the paper, at the same time viewing the pencil-point directly. The *whole* pupil of the eye is available for both images, the diaphragm on the apparatus being considerably larger than the pupil. It may be necessary to balance the illumination either by subduing the light in the microscope or by increasing it on the drawing-paper. It will generally be found that when the object is in a luminous field the light on the object (especially with lamplight) may be advantageously subdued by ground glass or similar means. The eye may be removed as often as required from the camera, and the work recommenced without the slightest shifting of the image; and with properly balanced illumination, fully shaded drawings can be made with very little practice. The drawing-paper should in every case be placed at the distance of distinct vision, either using spectacles or not. If the vertical position of the microscope be preferred, the drawing-paper may be inclined 45°, either in front or at the side of the instrument. For very accurate drawings in all azimuths, the drawing-paper should of course wholly coincide with the plane of the optical image, as with every other form of camera lucida. A spring clip is provided in which a screen of black paper may be put to shade the eye not in use.

This form of camera lucida can be modified so as to project the image at any desired angle. It can be used with the dissecting microscope or hand-magnifier, also on a stand for architectural or mechanical drawings.

THE HISTORY OF A BUCKET.

In an interesting paper on the history of a bucket, recently read before the Warrington Literary and Philosophical Society, Mr. T. Morris said:—There is not the slightest doubt about the sheet iron being manufactured in South Staffordshire from which the first bucket was made, and this will be my reason for describing the treatment and passage of these ores from the stone to the very useful domestic article under consideration. The first step taken after the clay iron ore is brought out of the pit is to make it up into heaps with roughly-built sides; in this form it lies for a time to weather, the action of the sun and rain causing a large amount of adhering useless matter to fall from it. It is afterwards calcined, a process technically called "roasting." This consists in the application of a moderate heat, whereby the more volatile components of the ore, such as carbonic acid, sulphur, &c., are expelled. This is effected by spreading on the ground a stratum of coals to a depth of about eight inches, over which is laid a layer of ironstone to a depth of about 6ft., interspersed with small cinders and coke dust and covered with small coals. The coals being set on fire combustion will go on for nearly a month, when the cementation is complete. The modern method of performing this roasting process is in a kiln, the coal and ironstones being put in at the top, and the roasted ore taken out at the bottom. The next operation is the conversion of the calcined ore into metal by the application of a white heat in a furnace. This process is called smelting. As will be readily understood after what we have said on ores of iron, after the roasting process they consist of an oxide of the metal, combined with some earthy matter in very various proportions. If these ores were fused alone, anyone having the least knowledge of chemistry will at once perceive that they would be formed into glasses, the properties of which will vary with the composition of the ore, but retain no metallic character. The method of proceeding, therefore, must be to intermix the ironstones with such substances as during the process of fusion will combine with the oxygen and earthy matter of the ore and leave the metal free. The early metallurgists knew no fuel but charcoal, but this was fast getting exhausted when Lord Dudley, of South Staffordshire, in the year 1650, or about that time, got letters patent to use pit coal. Ever since then the ordinary coal when converted into coke has been found to be the most useful and economic fuel. From the great affinity of this coke or carbon for oxygen, it is selected as the proper substance for separating the metallic base from the oxygen. The nature of the other substances to be employed i separating the earthy matter of the ore is deter mined by the species to which that earthy matt belongs. In the case before us limestones are use they being the best flux to form glasses or slag with the earthy matter of this argillaceous ore. T give the construction of a smelting furnace will b out of place. It will be sufficient to say that th ores, coke, and flux are charged into the top and a acted upon by the heat rising up from the low part of the furnace, the combustion being acce erated by air being blown into the furnace und pressure. The oxygen of the ore combines with th carbon of the coke, the limestones with the alumin silica, &c., and a portion of the carbon with th metal, which being the heaviest falls down to th lowest part of the furnace. There are suitab openings in the lower part of the furnace, one at th bottom of the hearth which is opened at fix periods to allow the molten iron to run out, and o at the top of the hearth or "bosh," as it is calle from which the slags are continually flowin Whilst this lowest part of the furnace is filling wi iron by the fusion of the ores the men are engag in making rough moulds in sand to receive th metal, which when cast is commonly known as p iron; by metallurgists it is called the carburet of iro Thus what it took nature myriads of years to form converted in a few hours by the knowledge a handiwork of men into the most useful met known. It is the finished and sheet iron maker th we have now to do with. For a few minutes w will follow him and see what he does with th useful metal. It is of no moment to describe th puddling furnace, only to say that this is the fir stage the finished iron maker passes it through, a that the furnace has two compartments, one calle the grate and the other the hearth, the two bein divided by a bridge composed of iron plates, wi firebrick on that side of them next the fuel part, a on the other side where the metal is put a lining (fettling) of a refractory material, the latter bein blackband ironstone after being calcined, or sa

---

* Journal Royal Microscopical Society.

It was well enough for observers of past generations to describe colours superficially: but spectrum analysis has shown us that we may gain as perfect a knowledge of the chemical constitutions of stars as a chemist can of the identity of a metallic salt on his laboratory table.

The Chairman said he thought Professor Smyth had attached too much importance to what was, after all, but the expression of opinion from an individual member. The Society was glad to encourage observational astronomy, and to publish the results of such observations; but they ought not to be held responsible for errors that might be contained in those observations. With regard to tracing the colours of stars up to their places in the spectrum, that might hereafter be done; but at present it was impossible, as the amount of work entailed on the management was enormous. The suggestion had, however, reminded him that Dr. Huggins had kindly presented the Society with a complete series of his works, and had expressed his sympathy with the objects of, what he was pleased to term, "the infant Hercules."

Mr. Espin then read a paper "On a New Theory of the Cause of Stellar Variation." The star [illegible] Pegasi is a known binary. At the time of its discovery, the components were a second of arc apart; but in 1866 it was observed to be single by Secchi, since which time it has widened, being half a second apart in 1875, and was observed by myself as strongly elongated, if not divided in Oct., 1880. Mr. Pocklington, while observing stars, at my request, in this region, found the magnitude as 5·3. Now in the *Uranometria Argentina*, it is classed as 5·5, and yet in the two neighbouring stars, 34 and 35 Pegasi, Mr. Pocklington's estimate agrees exactly with Dr. Gould's. This result was so very curious that I measured it with the photometer on Dec. 6, 1883, and the resulting magnitude came out as [illegible]·4. It at once suggested itself to me that the variation in light might be due to the closing and widening of the two stars, and I believe this may account for the long periods of fluctuation in many stars: if so, we have a new method of determining which are binary stars without the use of the telescope.

A paper by Mr. W. F. Denning, F.R.A.S., was read on the "Meteors of February [illegible]":—During the night of February [illegible], 1877, I observed two well-defined meteoric showers from the points.

R.A. [illegible] Dec. 24 N.
R.A. [illegible] Dec. [illegible] N.

The meteors were rather bright and moved in swift courses. I am desirous of calling attention to those shown, in the hope that they may be re-observed during the present year. As to the former shower, it appears to have been seen by several observers, as follow:

	R.A.	Dec.	
Jan. 1-25.	[illegible]	[illegible]	Greg and Herschel.
Jan. 4-11.	[illegible]	[illegible]	Tupman.
Feb. 2-10.	[illegible]	[illegible]	Tupman.
Feb. 6.	[illegible]	[illegible]	Schiaparelli and Zezioli.
Jan. Mar. [illegible]	[illegible]	[illegible]	Meteor Cat. [illegible]

It is obviously one of those radiants which, though of long endurance, yet display special activity on certain nights.

Mr. E. F. Sawyer, Cambridgeport, sent an interesting account of the occultation of [illegible] Libræ. When the star had reached the dark edge, its sudden disappearance was looked for; but the star apparently projected itself on the dark limb of the moon until it had very nearly advanced inside the dark edge.

Papers were read by Mr. W. S. Franks, F.R.A.S., Mr. W. [illegible], and others, and the meeting adjourned at [illegible].

Cinchona Bark.—In the year 1882 the imports into the United Kingdom amounted to [illegible], against [illegible] in the previous year. The total value of the imports for 1882, although upwards of [illegible] more were imported, shows a diminution of [illegible]. Of the different countries where the bark is cultivated, Ceylon is by far the most important, but it is said that Bolivia, Java, and Southern India are making great efforts in the same direction. As an easy classification of the barks produced in the different regions of South America, Mr. Hamilton suggests the following:—(1) Officinalis (crown bark, or "[illegible]" bark), as it is classified in [illegible], rich in quinine; [illegible] cinchonidine, or "red" bark, rich in cinchonidine; [illegible] Columbian barks, comprising [illegible] lancifolia, and Carthagena [illegible], both rich in quinine and [illegible] Pitayo, rich in quinidine and [illegible], although not a true cinchona, contains quinine, quinidine, cinchonidine, and the new alkaloid [illegible] in some cases. (4) [illegible] and (5) [illegible], rich in cinchonidine, and (6) Calisaya [illegible] bark, very rich in quinine and [illegible] cinchonidine.

SCIENTIFIC NEWS.

THE most noticeable feature in connection with the Comet Pons-Brooks at present recorded is the remarkable change in brightness which it appears to undergo now and then. Dr. Müller, of Potsdam, reports another sudden increase of brightness on January 1st, for at one observation he made on that day the nucleus was large and diffused, the brightness agreeing well with the calculated light-curve. Two hours afterwards, instead of a diffused nucleus he found an almost stellar point, equal in brightness to a seventh mag. star. Two hours later the comet had recovered its normal appearance. The time would be between 7 and 9 G.M.T., Jan. 1, and it would be interesting to learn whether the change was noticed by other observers.

At a recent meeting of the Physical section of the Royal Dublin Society, Mr. Howard Grubb, F.R.S., read a paper on a "New Form of Equatorial Telescope," in which the observer is placed under more favourable conditions—in fact he may be as comfortable as the microscopist. He described some forms of instruments of a small size which he had constructed, and then showed on the screen by means of a lantern a design for a colossal instrument, in which all the optical and large mechanical parts were in the open air, except the eyepiece, which was situated in a room on the top story of a house. The observer was represented seated in an easy chair, beside which were two handles controlling hydraulic machinery by which all the movements of the great telescope were effected. The French have accomplished something of the kind with their bent, or elbow, equatorial, but at enormous cost and much complexity; whereas Mr. Grubb's device can, it appears, be produced for about one-third the price of the usual form.

The Rev. Dr. Haughton, F.R.S., read a paper the other night before the Royal Geological Society of Dublin, on the remarkable sunrises and sunsets. So far from accepting the volcanic dust hypothesis, Dr. Haughton contends that the phenomena were merely intensifications of the ordinary phenomena of twilight, and did not point to exceptional reflecting powers in the atmosphere.

Mr. N. E. Green, F.R.A.S., lecturing at Ealing last week, adopted the volcanic dust hypothesis, as he found the others untenable; the meteoric dust theory being negatived by the fact that the sunsets occurred before Biela's comet was due. Mr. Green said if dust from the Java volcano really got to the upper regions of the atmosphere, which was less attached by gravity to our earth, it might come into a stratum of air lagging behind those nearer the earth, and thus its slow arrival from the east would be accounted for.

At a meeting of the Royal Society of Edinburgh, Mr. John Aitken read a paper on "The Dark Plane in Dusty Air," in which he said that the downward dark plane was caused by the separating action of gravitation, but that the tops and sides of cold bodies had no dust free spaces surrounding them; while the upward dark plane was produced by gravitation, by repulsion due to heat, and by evaporation and disintegration. By an application of electricity it was demonstrated how air was purified, the entire dust of the air being deposited on the sides of the vessel in which the experiment was made. A question of great interest was, how did the lungs keep working, considering the enormous quantity of dust in the air? The experiments he had made went to prove that the heat of the lungs tended to repel and to evaporate the dust particles, and thus keep the lung surface free from the contamination of dust. The tendency which dust had to leave hot surfaces and settle upon cold ones had suggested to him the possibility of making an air filter on thermic principles. Referring subsequently to the sunsets, Mr. Aitken thought that the blues and greens which had been seen at the same time as the reds, proved that the rays of light had been reflected by dust, and for that reason he thought the remarkable sunsets were caused by dust, and not by aqueous vapour.

Our readers will be sorry to hear that Mr. John Brown, of Belfast, while experimenting in the chemical laboratory of Trinity College, Dublin, was severely injured by an exploding retort. A piece of glass entered one of his eyes, and the surgeons have unfortunately found it necessary to remove that organ.

The Gresham Lectures on Astronomy will be delivered in Gresham College, Basinghall-street, at 6 p.m., on Feb. [illegible] and [illegible]. The subjects will be the planet Saturn, Comet Pons-Brooks, the recent Sunrise and Sunset Phenomena, Circumpolar Constellations, the Dragon, Cassiopeia, &c.

Dr. Angus Smith's next report to the Local Government Board, as one of the Inspectors under the Rivers Pollution Prevention Act, will contain matter which will be regarded as highly important by all who take an interest in microbiology in general, and in the germ theory of disease in particular. Dr. Smith's recent researches have led to the discovery that in all natural waters sugar ferments and hydrogen gas is given off. The proportion of hydrogen given off varies with the organic impurity of the water, from the mountain stream to the worst sewage, so that the proportion of hydrogen evolved appears likely to prove a quantitative test of the activity or virulence of the microbes present in the water.

Mr. E. A. Cowper's lecture on the "Steam-engine," one of the series on "Heat in its Mechanical Applications," delivered before the Institution of Civil Engineers, was illustrated by an interesting collection of models and drawings, showing the progress of the steam-engine from the earliest Newcomen 1711 down to the monster marine engines of the present day.

At the last meeting of the Chesterfield and Derbyshire Institute of Engineers, the adjourned discussion of a paper on the "Principles of Electric Lighting and Transmission of Power by Electricity" was taken. The author of the paper stated that Derbyshire was behind every other district with regard to electric lighting, but was promptly informed by Mr. Stokes, inspector of mines, and others, that the mining engineers of Derbyshire were the very first to experiment with it—and condemn it. If they could have electricity in a vessel that could be carried about it might answer; but wires in a pit had failed.

According to Sir W. Thomson, the Lalande-Chaperon cell is inferior to the Bennett in E.M.F., but is superior to every other form with which he is acquainted in its remarkable capacity for giving strong and steady currents from plates of moderate area. The Lalande-Chaperon cell was illustrated and described on p. [illegible], Vol. XXXVII.

A pupil of the late Prof. Rolleston, at Oxford, has been chosen to succeed the late Mr. W. A. Forbes, as prosector to the Zoological Society of London. Mr. Frank E. Beddard has been employed on editorial and other work connected with the reports of the *Challenger* expedition, and has been intrusted with the examination and description of the Isopoda collected during the voyage.

M. Bouley has been appointed vice-president of the Académie des Sciences of Paris. As the natural consequence he will become president in 1885.

The *Guardian*, discussing the resistance of disease germs to disinfectants, remarks that it is extremely probable that the disease germ of small-pox is present in the form of living bacilli in the fluid which is the principal bearer of the infection—the lymph removed from the pustules. The degree of vitality of the bacilli varies in the different kinds of lymph, the lymph from cow-pox losing its capacity for infection much more readily than the so-called human lymph.

On Wednesday evening, our contributor, Mr. W. J. Lancaster, delivered a lecture on the "Political History of Birmingham," illustrated by specially-prepared lime-light views, before the "Forward" Liberal Club at Birmingham.

As wood changes under the influence of the air, growing brown and consequently diminishing the durability of the paper in which it has been employed, it is of importance, for the dealer and consumer, to be able to ascertain whether a given sample of paper contains woody fibres or not. For this purpose a solution of sulphate of aniline, or a mixture of one part sulphuric acid, three parts nitric acid may be employed. Either of these solutions produces immediately a yellow colour upon the paper if it contains wood, the depth of the shade increasing as the proportion of wood increases.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor *of the* English Mechanic, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

THE NEW COUNCIL LIST OF THE ROYAL ASTRONOMICAL SOCIETY—VOL. XLVII. OF THE R.A.S. "MEMOIRS" — MARS, JUPITER, AND SATURN — TELESCOPES OF LONG FOCUS — ANEROID BAROMETER — "FAME'S PENNY TRUMPET"—CITY GUILDS AND BROMPTON GRASPING — INCHES v. CENTIMETRES — RED STARS AND AN UNREADY REWARD —BLUE MOONS—SUNRISE AT THE CLUN STONE CIRCLE — CALCULATION OF COMETARY ORBITS.

[22289.]—In common, of course, with every Fellow of the Royal Astronomical Society, I have just received the "House-List" of the Officers and Council of the Society for the ensuing year. It is simply a repetition of the old story—by a shuffling of the cards between the Vice-Presidents and the ordinary Members of Council, substantially the current list of office-holders reappears. One new name, however, will certainly be welcomed by the Fellows: it is that of that thorough astronomer and single-hearted man of science, Colonel Tupman, who is nominated as one of the secretaries. I can only express a hope that one or two of the paltry traders upon science with whom Colonel Tupman will sit will appreciate the honour done them by association with the man, whose disinterested zeal for the promotion of astronomy prompted him to carry on the Computations of the 1874 Transit of Venus at his own cost, after the allowance from the Treasury had ceased. I am most sincerely sorry, though not surprised, to note the disappearance of Mr. Barrow's name from the office of treasurer. Of course the reason is not far to seek. He does not dine with the wire-pullers in the council who aid and abet the South Kensington ring, and so, of course, had to be got rid of. On the whole, though, I have seen worse lists, and if voters will only run their pens through the names of actual members of that most paltry imposture, "The Committee on Solar Physics," substituting for them those of such well known and independent men as Mr. G. F. Chambers, Sir James Cockle, Sir Edmund Beckett, Mr. Franks, or Mr. Green, I do not think that the interests of astronomy, as contradistinguished from those of certain persons, will be likely to suffer at the hands of our new executive.

Apropos of the Royal Astronomical Society, the volume of its *Memoirs* (XLVII.) just issued contains much that is of interest to the astronomical student. To begin with: no one can, I think, read the detailed accounts of the various observations of the last Transit of Venus without being forcibly impressed with the idea of their untrustworthy character as a means of determining the Solar Parallax with anything like rigid accuracy. It is quite extraordinary to read of the different aspects presented by the same phenomenon to men observing almost side by side. Some appear to have seen nothing whatever in the shape of the notorious "black-drop"; others to have observed it in its most aggravated form: while in at least one case, so far from a ligament connecting the planet's limb with the dark sky beyond that of the Sun, the limb of Venus appeared at egress actually to push, as it were, the bright limb of the Sun before hers! Any attempt to collate the times of occurrence of the various phases described in such extraordinarily diverse terms must, it would seem, be almost futile. In fact, it can only be by an ingenious process of "cooking" that they can be rendered susceptible of comparison at all. Passing from this subject, I need merely give the title of a paper by Mr. S. W. Burnham ("Double Star Observations made in 1879 and 1880 with the 18½in. refractor of the Dearborn Observatory, Chicago, U.S."), to indicate its high interest and value to every one engaged in the study of the stellar heavens. Mr. Plummer, of the Oxford Observatory, has been reinvestigating the question of the solar motion in space, from a discussion based upon the proper motions of stars in the Southern hemisphere. A similar discussion was undertaken by Mr. Galloway about 40 years ago; but Mr. Plummer has employed the improved and more accurate proper motions given in Mr. Stone's admirable "Cape Catalogue." He comes to two conclusions worthy of note: the first being that it appears probable that, *on the whole*, proper motion is a measure of stellar distance; and next, that the direction of the solar motion in space is towards a point in the heavens situated in R. A. 18h. 24m. 32s., and declination 26° 31′ North. This is in a very blank region of Hercules S. by W. of Vega. Mr. Dunkin, it will be remembered, from a discussion of all the most trustworthy results since the time of Sir Wm. Herschel, placed the apex of the solar motion in R.A. 17h. 34m. 56s., and declination 25° 0·5′ north; a little to the S.E. of λ Herculis. And last, though by no means least, I must mention two papers by Professor Pritchard, one on the "Measurement of Lunar Photographs"; the second on the "Photometry of the Brighter Stars North of the Equator." I have spoken formerly in such very definite terms in these columns of Doctor Pritchard's connection with the miserable XLth Volume of our *Memoirs*, that I shall assuredly not be suspected of being prompted by any feeling of private friendship or wish to flatter the Savilian Professor when I say that both these papers—and notably the latter—are of great and enduring interest and value, and give the results of an enormous amount of real hard scientific work. The remaining paper in the volume is one by Mr. H. C. Russell, the Government Astronomer of Sydney, who has been remeasuring Herschel's Cape Stars. Its use will be chiefly confined to observers in the Southern Hemisphere.

If evidence were needed of the care and accuracy of the observations of "M.A.," it would be found in his letter (22239) on p. 427. As far as my own experience goes, his description of the telescopic aspect of Jupiter and Saturn is rigidly accurate. The "fine mist" of which he speaks is certainly essential for the finest definition of Jovian detail. By far the best drawings I have ever made of Jupiter in my life have been made when a faint haze overspread the sky. Under such conditions the colouring of the planetary markings becomes wonderfully accentuated: the general glare of Jupiter's surface, so to speak, diluting it, under normal circumstances. The tints of the ball and rings respectively of Saturn, which "M.A." describes, are identically those which I see myself. In connection with Mars, I can only repeat what I said in letter 22097 (p. 301)—viz., that I have had splendid views of Areographic detail with a higher power than I can, generally, employ on Jupiter. I do not know, though, that the *limb* of the planet was particularly sharp.

With reference to query 52725 (p. 437), I would point out to Mr. Mee that, inter alia, the degradation of light by the increase of magnifying power is a very operative factor indeed in limiting the amount of amplification. Let us take his own hypothetical telescope of 2in. in aperture and of 30in. focal length, then, as he says, with an eyepiece of ¼in. focus, the linear magnifying power will be 120. Now, the aperture of the object-glass and the eyepiece remaining the same, let us double the focal length of the former, and we shall, in the result, get a power of 240. But the image (say, for the purpose of illustration, of Jupiter) formed in the focus of the objective will be of twice the diameter of that projected by the object-glass—of the same diameter—when its focus was only 30in., and hence will only be one quarter as bright as it was with the shorter-focussed glass. Double the increased focus, in other words, substitute a 2in. object-glass of four times the original focus, or 120in., and we degrade the light of any given part of the resulting image to the $\frac{1}{16}$th of that of the original one, and so on. Of course, the ultimate total loss of light of image, when it reaches the eye, is compounded of that which it jointly sustains from both the object-glass and the eyepiece. An extremely long focussed object-glass gives a large and very dim image for the microscope which we call the eyepiece to magnify; an objective of short focus, a smaller and brighter one; although this involves increased loss of light and greater aberration from the necessarily small lenses, with their deep curves, of the ocular. A great art of the practical optician is so to proportion these two elements as to afford the best result.

"C. J. N." (query 52741, p. 437) should by all means send his aneroid barometer to a practical philosophical instrument-maker for repair, and not even to a jobbing jeweller, who sells spectacles, &c., and calls himself an "optician." A good aneroid is far too delicate a piece of mechanism to be tinkered with by an amateur, or, in fact, by any-one but a skilled workman.

I hope that everyone to whom the honour and purity of science are dear will get the collection of poems by that inimitable humourist, Mr. "Lewis Carroll" (over whose "Alice in Wonderland" and "Through the Looking-glass," so many hundreds of thousands of us have laughed), if it be only for the sake of the one entitled "Fame's Penny Trumpet." The appositeness of the reference in one of the verses to a certain pictorial advertisement which was recently "got into" *Punch*, will strike the reader at once; while the scathing denunciation of the quacks and humbugs, whose slimy flattery of each other has no other object than the deception of the public and the filling of the pockets of their Mutual Admiration Society (Limited), must commend itself to every honest man. Mr. Lewis Carroll has never done a greater public service than he has in showing up the scheming and mendicant Cabal, whose partial success even, speaks but poorly for the state of popular knowledge in this country; and who, if scientific information were a little more widely diffused among the governing classes, would either have to transfer their cadging tactics to some other clime, or work honestly for their living here, like other people.

It is to be hoped that every one of the Civic Companies which have so lavishly contributed to the funds of the City and Guilds of London Institute, will read, mark, learn, and inwardly digest, the "Report of Sub-Committee A to the Executive Committee on the Organisation of the Central Institution," which was presented on January 21st of the present year. They will learn from it, now it is too late, how effectually they have handed themselves over to the domination of the South Kensington ring. At the time of the inception of the whole scheme efforts were made by certain members of the committee, representing those who actually provided the funds, to have the buildings of the Central Institute erected on some portion of the Victoria Embankment. It was known to (but suppressed by) at least one member of the committee that ample land for the purpose could have been obtained in the neighbourhood of the Savoy; but it was felt that the establishment of the headquarters in such a locality would have thrown too much power into the hands of the men whose sole function was to find the money, and who had already shown too much independence of the Brompton clique by appointing Mr. Magnus as organising director and secretary instead of Mr. Redgrave. Heaven and earth were therefore moved to get the collegiate buildings of the Central Institution erected at South Kensington; the "genteel" element was paraded in force, the snobbish instincts of such as could be worked upon were freely appealed to, and all the notorious sickening trade cant and "Albert-the-Good" business employed without stint. In the result, the representatives of the Guilds proper surrendered themselves to the astute schemers who had worked throughout in the sole interest of South Kensington, and it was decided to erect the Central College within the charmed area owned by the Commissioners of the Exhibition of 1851. It needs no supernatural intuition to discern in the Report now lying before me, the hand of some very active members indeed of the Brompton ring. After reciting the general objects for which the Institute was established, and enumerating the various professorships which it will be necessary to establish, this instructive document goes on (on p. 17) to treat of "Management"; and here we find that "2. Any lecturer holding an annual appointment, and giving a separate course of instruction, may be appointed by Sub-committee A as a member of the Board." The meaning of this is almost too obvious to need pointing out. Merely as a matter of course, this is a device for adding to the power of the ruling clique in the Direction. These professors must, under existing circumstances be, one and all, the creatures of South Kensington; and their votes will, of course, be used to crush the independent minority, who still weakly think that, because they merely represent those who are paying for the whole thing, that, hence, they have some right to a voice in the employment of the money! It is perhaps, though, in connection with such employment that this precious report is most noteworthy. Turning to p. 19 of it, I find that "For the efficient carrying out of the above scheme, it is believed that a sum of £15,000 a year will be required, part of which would be provided by the students' fees." This amount is made up as follows:—

Salaries of Professors, Lecturers, and Demonstrators	£8,700
Apparatus and Material	1,500
Clerks, Porters, Attendants, Servants, &c.	1,500
Printing, Advertising, Stationery, &c.	1,300
Repairs, Rates, Coals, Gas, Insurance, &c.	2,000
	£15,000

Deducting £5,000 as estimated fees from students, this leaves £10,000 to be provided for; and, assuming that the current expenditure (as a whole) for 1884 does not exceed £18,500, this, with the present annual receipts, would only leave an available balance of £6,000 for the Central Institute, so that there would remain at least £4,000 to be provided for. Now I hear, in a very roundabout, but, I am satisfied, perfectly trustworthy, way that, at the Committee meeting at which this report was pre-narrow stripes, whereof each alternate one retards light half a wave-length more than its neighbours, the spectra are *fourfold in brightness*. Now these also would still image lines, though falsely. The application to transparent microscopic objects need not be pointed out.

Yet the more we understand the true relations of these spectra, and their optical effects, the truer will our interpretations become, within, at least the limits of microscopic vision, and the more certainly shall we be directed to methods of manipulation which may truly interpret the phenomena. Taking merely the theory of the matter, let us consider the case of Fig. 2, where only the lines A A and B B really exist, but C C are apparent by the illusory spectra of the narrow spaces between A B, A B. It is plain we have means, if our suspicion as to the existence of C C C is awakened, of clearing it up For we can stop off not only the central pencil, but those inner spectra which give us the coarsest intervals A A A. This will bring into stronger relief the spectra representing the next widest spaces, B A, B A, and thus we may correct the former result. Also it is obvious that any skilful manipulator with a knowledge of physical optics, by stopping off central pencils, and, when necessary, inner spectra, might bring into stronger relief the much fainter spectra caused by fainter and finer striations, which were before "drowned," as it were, in the coarser phenomena. Mr. Stephenson proved this in the case of *P. angulatum*, bringing out minute patterns, when the central pencil was stopped off, which had never before been seen.

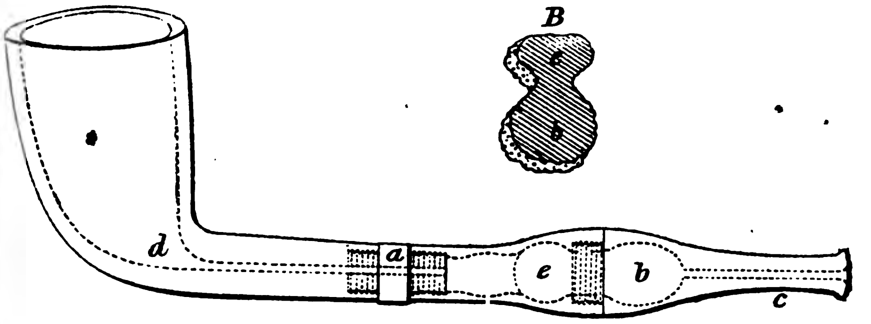
It is also evident why so much is learnt from various incidence of the light; but it will also appear that this should be studied more gradually than most mirror arrangements permit. As a rule, I see microscopists adjust for one obliquity, and make their observation; then try another. It would rather appear that continuous observation under a steadily increased obliquity, must be necessary to good interpretation; and that even then a competent knowledge of the physical phenomena of optical gratings is necessary, as well as a careful collation and comparison of the appearances with those presented under similar treatment by coarser objects, of which true dioptric images can be obtained. But even then it will be only a matter of interpretation more or less correct. All we know of *A. Pellucida* is, that there are striæ, or ridges, or something, occurring at intervals of so many to the inch. It is obvious they cannot be mere lines, as they appear to us; but as any "form" must involve another set of lines of at least double the minuteness, and probably far more, what is there can never be known, except from analogy and comparison with larger diatoms. As a rule we must get lines only in minute structures, and, as a rule, that appearance is certainly false. Nevertheless, the variations in distance between the spectra under gradually increased obliquity, and their consequent image-results, appears the most likely general method of ascertaining the true *proportions* of distances between striæ not all equi-distant, while the successive stopping out of the inmost and brightest spectra appears the most promising general method of revealing those fainter spectra which may lie hidden behind, and which reveal some periodic variation in structure at the distances of the apparent lines.

I almost feel as if I ought to apologise for this, since it will be read by those who know fully as much of optics, and infinitely more of microscopy than myself. The only microscope I possess is of the simplest, and I have only been able to repeat the simplest of Messrs. Abbé, Stephenson, and Crisp's beautiful experiments, not having either appliances or time for the more delicate ones. Hence, it may seem presumption to remark at all upon matters which may be presumed to belong solely to skilled manipulators. I can only say that the matter appears to me also to belong to the physical theory of light, from which side alone I have approached it; and that a clear understanding of the theory would appear to me to give valuable guidance towards manipulation. Whether or not any may gather hints from the above considerations, however—and even if I am proved to be wrong in any point—discussion of such points can hardly fail to become practical and interesting.

I had meant to add a little upon aperture, not feeling at all sure that the last word has been said about that yet, and believing that though much misused and misunderstood by some past opponents of the new theory, there yet remains something in the 180° idea. But even if time permit, I had better see the reception of these remarks before venturing upon any more.

Jan. 26. **Lewis Wright.**

COLONEL ROSS'S CONDENSING SMOKE-FILTER PIPE.



[22293.]—As there seems to be some misconception about the trouble in using the tobacco-pipe invented by me, which came out after I left Lonm, I would ask you kindly to publish the followg directions and sketch, by which your readers ll readily perceive that there is no more trouble in smoking it than there is with the ordinary pipe, whilst, on the other hand, two enormous advantages are gained. (*a*) The smoke is entirely divested of the offensive volatile oil containing the nicotine, being thereby rendered wholesome instead of injurious to the smoker, and quite inoffensive as regards the smell communicated to the furniture of a room, or, indeed, in a great measure to the pipe-case itself. (*b*) The pipe, if these directions as to manufacture and management are attended to, scarcely ever requires cleaning—say once a month—and then only about an inch and a half of the stem next the bowl, which can be done in ten seconds with an old hair-pin twisted. The sketch is taken from the pattern briar made for me to try, by Messrs. Frankau and Co., lying opened on the table before me. F. and Co. write to me that it will shortly be sold (to the trade, I suppose, as they are only wholesale makers), at 24s. per dozen, which will make it about 3s. per pipe to the smoker.*

The principal parts of the pipe are: *a*, the ivory non-conductor, screwing into the briar (*d*) towards the bowl, and into the vulcanite (*b*) towards the mouthpiece; *b*, the filter-chamber containing the sponge, divided by a screw about its middle; and *c*, the mouthpiece. If the pipe is managed as follows, the only part requiring cleaning once a month is the tube or bore of the briar part, from *d* to *a*. B is a sketch of my pipe-sponge, natural size. After a smoke, unscrew the chamber *b*, and press the small end of the now saturated sponge, *e*, *kept in its chamber*, against a wall, or anything where the smell does not matter; this will squeeze that part of the sponge nearly dry. Now blow strongly through *c*, and the pressure of the blast will force a great part of the volatile oil, &c., contained in the part of the sponge *b* into *e*, which is to be squeezed against the wall as before. A few repetitions of this simple process (which does not occupy half a minute, and, of course, leaves the fingers perfectly clean) will suffice to *completely* empty the whole sponge of its volatile oil, leaving a brown pasty substance behind, which can be completely dissolved out of the sponge (after two or three months' smoking, but even then it is not *necessary*) by putting it in a few drops of alcohol—or, better, ether—for a minute or so. If a sponge requires squeezing whilst the smoker is out walking, the most effective and rapid method is to drop it on a stone pavement or path, and squeeze it thoroughly with the foot by standing upon it. The "juice" is so volatile that the sponge, after one or two such squeezes, is dry enough to take up in the fingers and reinsert in its chamber without soiling them in the least degree. If the pipe is unscrewed, and the outer half of the sponge exposed to the air at night, it will be found perfectly dry in the morning and ready for work.

The makers have a bad habit of *cementing* the two screws at *a*, which is a *great* mistake, as the smoker then cannot get properly at the only part of his pipe which can become foul—viz., from *d* to *a*. These screws should be left to unscrew quite easily, so that the smoker can, if he requires, blow strongly from *a* to *d*, and clear away any obstruction.

The sponge should be cut with a pair of scissors (I fear mine was done very roughly) so as to fit with a thin part into the screw *e b*, the larger part of course being contained in *b*. It need *never be moved* from its chamber *e b*, except, as above mentioned, to be cleaned once in three months with ether. Surely there is no "bother" in this! Yet, people have written to me that "they prefer using cotton wool or charcoal" or Heaven knows what, "to do away with the bother of cleaning the sponge." **W. A. Ross.**

Hotel Beau Site, Monaco, Jan. 18.

KNEE BREECHES v. TROUSERS.

[22294.]—YOUR quotation from the *Lancet* of the 19th inst. misses, as a correspondent of that paper points out in the following number, one reason, and he thinks the chief reason, for the preference, and certainly the one that leads the labourer to transform his trousers into rude knickerbockers by pulling up the legs two or three inches, and then confining them tightly with straps just under the knee. Trousers interfere greatly with knee action at all times, particularly in walking, and most especially in the case of the agricultural labourer, who, being burdened with thick, hard boots, which allow scarcely any play at the ankle or instep, and being obliged to step high to get over the clods, has to flex the knee more sharply than other walkers. Trousers hanging free from the hip, there is always in the garment the exact length of the limb between hip and knee, and this entails a tiresome and embarrassing pull at the knee when these joints are constantly brought into action together. Breeches, on the contrary, being confined at the knee, a sufficient length can always be obtained above to allow of perfect freedom of action. I always wear breeches for a long walk, and so I think would many others if the comfort of doing so were better known. Let anyone imitate the labourer by pulling up his trousers two or three inches, and then fasten them firmly with tape just below the knee, and he will get a moderate appreciation of the comfort of breeches for walking and sitting.

Another advantage I may mention, as it is somewhat of the nature of a wrinkle for walkers. Everyone will have found how wet one gets about the knees in walking in rain, and the reason will be evident to everyone. At any time breeches may be dried without changing if you first place some folded paper (a newspaper) inside the garment between it and the limbs.

Lechlade, Jan. 21st., 1884. **W.H. Bo.**

CALICO PRINTING—REAGENTS FOR ALKALIMETRY — FATTY ACIDS — ALUMINIUM — EXTRACTING ANILINE COLOURS—THOUGHT READING BY MACHINERY — PERMANGANATE STAIN IN CARPET.

[22295.]—IN a query headed "Calico Printing" (No. 52858, page 460) information is requested as to the mode of making a certain liquor largely used in calico printing, of which one of the constituents is castor oil. I presume the querist refers to what is known as "Turkey-red oil," though his description is not very explicit. Several distinct preparations are used, and the one to which "R.W." refers is probably that made by mixing castor oil with sulphuric acid previously diluted with about one-third of its bulk of water, and leaving the mixture over-night. The acid is then washed away by a solution of common salt, and the fatty acids treated with ammonia, or a mixture of ammonia with soda or potash. The resultant Turkey-red oil consists chiefly of ammonium sulpho-ricinoleate.

A "Reagent" for use in alkalimetry (query 52831, page 459) which is suitable for all conditions has yet to be found. The relative delicacy of methyl orange, phenolphthalein, litmus, &c., depends much on the presence or absence of extraneous salts. A most valuable series of experiments on the subject of indicators has been contributed to the *Chemical News* (Vol. XLVII., pages 123, 135, and 184; and Vol. XLIX., pages 35 and 38) by Mr. R. T. Thomson. He shows that in solutions free from salts litmus and methyl orange are about equally delicate, but are far outstripped by phenolphthalein and phenacetalin. Phenolphthalein is wholly useless in presence of ammonium compounds. The behaviour of the indicators with various salts of neutral and acid constitution is exceedingly interesting. Thus sodium thiosulphate ("hyposulphite") is neutral to all four indicators. Na_2So_3 is alkaline to methyl orange, but neutral to rosalic acid and phenolphthalein. NaHSO$_3$ is neutral to methyl orange, but acid to the two latter indicators. Litmus and phenacetolin are useless for the titration of sulphites. As a rule, it will be found that methyl orange is indifferent to weak acids, and hence it may be used for titrating the alkali in sulphides, carbonates, silicates, borates, &c.; while phenolphthalein is affected by the weakest acids, and is valuable for titrating fatty and resin acids. If "Brine" is interested in indicators, he cannot do better than study Mr. Thomson's papers.

---

* The pipes are now on sale at the Army and Navy, and Civil Service Stores, and, we believe, at the leading tobacconists. We have tried one, and think it does all Colonel Ross claims for it, and that henceforth our contributor's reputation as an authority on the *blow pipe* will rest on a double foundation. Careful adherence, however, to the instructions Col. Ross here gives is necessary, or purchasers may be disappointed, as no such information is given to buyers, and it is quite impossible to cleanse the pieces of sponge sold with the pipes in the manner Col. Ross directs. The end arrived at has long been a desideratum with smokers, and the means employed are used in the right place, and with the scientific knowledge one would expect in a chemist like Col. Ross. Instead of fixing a useless receptacle at the bottom of the bowl where the nicotine does not accumulate, Col. Ross intercepts its progress by what is really a process of cold distillation. The hot smoke, as soon as it passes through the non-conducting ivory ring, cools suddenly, and the nicotine is deposited on the sponge filter.—ED. E.M.

"Fatty Acids" (query 52450, p. 380) can be readily estimated by treating the fat with strong alcohol (neutral in reaction), adding a drop of phenolphthalein solution, and then adding decinormal caustic soda until a pink colour appears, which is not destroyed by shaking. 1cc. of decinormal soda represents 28·2 milligrammes of free oleic acid, 28·4 of stearic acid, 25·6 of palmitic acid, or 32·4 milligrammes of resin acids. If the sample of oil consists merely of free fatty acid and neutral fat, the quantity of the latter may be found by deducting the weight of fatty acid, ascertained by titration as above, from the total weight of the sample operated. If the mixture contain also some unsaponifiable matter, as hydrocarbon oil, it should be saponified by boiling with alcoholic potash; the alcohol boiled off, the soap dissolved in water, and the liquid repeatedly shaken with ether. The ethereal solution is separated, evaporated, and the residual hydrocarbon oil weighed. The weight, added to that of the fatty acids and deducted from the total, gives the neutral fatty oil in the sample; the process is of very general application, and capable of yielding accurate results. It is described in Vol. II. of my "Commercial Organic Analysis," which I believe the querist will find gives the fullest information on the commercial testing of fats; but, as it is quite out of print, he must obtain it from some public library or borrow it from a friend.

"Aluminium" (query 52529) is said by "Zelia Nalec" to have been deposited by him on gold and iron by an inexpensive process, and he wants to know if the discovery has any mercantile value. If the process is really simple and inexpensive, and he can get the deposit of any thickness, he has a fortune at his feet. But it is not the first time by many that the same claim has been made, and nothing has yet come of it. Similarly, I see that Mr. Grey's quotation of Mr. Weldon's demonstration of the impossibility of reducing aluminium by carbon has met with a rebuff from "A. E. S." (page 451). Nevertheless, until "A. E. S.", or some one else, comes forward in his real name, and produces aluminium in the way stated to be possible, I shall believe with Mr. Grey. There is more nonsense talked about the production of aluminium than any other scientific subject, now that perpetual motion and circle-squaring have been pretty definitely abandoned. What the *soi-disant* "practical" men cannot get into their heads is the fact that aluminium unites with oxygen with production of more heat than is evolved by the combination of carbon with the same weight of oxygen. If this is a fact, the reduction of aluminium by carbon must be hopeless. If it is not a fact, why do not "A. E. S." and other alchemists who believe as he does produce the metal they talk about? Carbon is cheap, sugar is cheap, and alumina is cheap, but where is their cheap aluminium?

I see on page 373 the question is raised whether "aluminium in a thin state" will oxidise? I had some leaf aluminium as thin as silver leaf for many years and it remained perfectly bright.

"Aluminium Sulphide" (query 52531, p. 352) cannot be produced in the wet way. It is formed by the action of sulphur on metallic aluminium at a red heat. It is decomposed by water into sulphuretted hydrogen and hydrated alumina. I do not think it could be prepared by heating aluminium sulphate with charcoal.

For "Extracting Aniline Colours" from paper (query 52559, p. 374) boiling alcohol will suffice. The aniline-red is readily removed in this way from the *Globe*, and no doubt the "Pink-un" and other coloured papers are tinted by the same means.

The "Thought Reading by Machinery" (query 52628, p. 396), I believe, on very good authority, to be effected by signs made by Mr. Maskelyne which, being seen by a confederate, are readily interpreted and made into automatic writing. The signs are of position merely, and not movements.

A "Permanganate Stain in Carpet" (query 52752, p. 437) can readily be removed by sponging with a solution of oxalic or sulphurous acid; or a mixture of acetic acied and hyposulphite would do. Better try on a small portion first, lest the colour of the carpet itself should be affected.

Sheffield, Jan. 26. **Alfred H. Allen.**

LATHE MATTERS.

[22296.]—In reply to "West Bromwich" *(22274, p. 4[illegible]), let me say that I shall feel pleasure in complying with his request if the Editor will grant space, and that my apology for not having* already done so is that so little can really be said about common lathe tools.

Fred. Carre (22275, p. 450) asks my opinion about the bed for a front slide-rest. He thinks that such a bed cannot be made with a gap. I confess I cannot see why not. Given the usual breadth of slide, it will be as capable of stretching two or three inches over the gap towards the face-plate, as is the usual form. I may, however, possibly misunderstand our correspondent, since he may be alluding only to the making of the pattern. If such is the case, let me assure him that, gap or no gap, such a bed is a very easy job: and if "F. C." and "O. V." are agreed that such a form would be desirable, I shall be pleased among "Letters to the Editor" to inclose a description, with sketches of the best way to make it. **J. H.**

[Our readers may be glad to know that in a private letter accompanying this "J. H." proposes future contributions, which have our hearty approval, and which will gladden the hearts of "West Bromwich," "O. V.," and a good many thousand more readers.—Ed.]

LATHES WITH FRONT SLIDE.

[22297.]—In reference to the lathe suggested by your correspondents, I can speak from experience as to the durability, as we worked a double lathe on that principle for many years by steam power, and it shows no trace of serious wear. It was used constantly for sliding short shafts, and was fitted with an automatic arrangement to stop at any required length.

The centres of this lathe are set over a little towards the front. The V is 1¼in. For amateur wear this would last 100 years without being resurfaced.

The long half-nut to move the saddle is not so good as the clutch-nut for several reasons. One great objection to this style of lathe is that the V-slot receives a great many chips, &c., and another is the general appearance is unsightly.

A far better plan suggests itself for amateurs who want to do other work besides screw-cutting, &c., and to whom the saddle-rest is a great nuisance. A back-geared lathe with the mandrel extended so as to receive nuts of various threads would cut screws to any required pitch with accuracy, and as quickly as a screw-cutting lathe, in a manner similar to that suggested by your correspondent, "J. L." some time ago.

The screw-cutting rest is carried on a strong round bar at the back of the lathe, and is instantly and easily lifted over when required. The appliance (called the former) is brought into connection with the hub by the same motion that brings over the rest into its place. Less than half a minute will convert the ordinary ornamental or wood-turning lathe into an effective screw-cutter.

When not required, the screw-cutting rest hangs down at the back of the lathe quite clear of the bed. Any ordinary back-geared lathe can be converted into a screw-cutting lathe which will give satisfaction.

Ordinary single-speed lathes would require to have a back-geared head to replace the ordinary head of their lathe. **Thos. M. Bear.**

Britannia Works, Colchester.

BEE-KEEPING.

[22298.]—Candy requires some care in using, as well as making. My experience is that it is best to run it, while hot, into an empty frame (holding 4lb. or 5lb.), and put that inside the hive. Last spring I placed it in cakes under the quilt, with unfavourable results; it dried too quickly, and also allowed an escape of heat. I should advise that candy be given early enough in the autumn for the bees to convert into syrup, and store away in the natural way (they always have to carry water to do this).

But why, it may be asked, not feed with syrup instead? Well, I treat the two plans side by side, putting a frame of candy in one hive, and feeding another with thick syrup through a bottle-feeder at the top. In 10 days the bees had converted and stored away all the candy; it was mostly sealed over, and the combs had nice patches of brood. In the other hive, the syrup hung out to dry as it were all over the hive, none sealed, and no brood: the candy is most trouble to make: but when once put in the hive, the work is done.

I cannot too forcibly state that no bee-keeper should require to feed in the winter; it should all be done in the autumn, when bees are active and able to store it away. Neither do I believe in the plan of giving them, late in the year, solid candy to cluster on; if given early, they can convert it all, and store it in the natural way.

Making the candy: The receipt given on p. 413 is right. I use a spoonful of cream of tartar to "break the grain." I place a sheet of newspaper on the table, and on this an empty bar frame: the frame is weighted down at the edges, and when the candy begins to stiffen pour in the frame.

In my district I find it a mistake to put flour of any sort in the candy. Bees should not be stimulated to breed in the winter, and with they get plenty of pollen from willow and l quite early in the spring.

I agree with "J. I. S." that Mr. Wils incorrect in stating that bees are partial to ce flavours in sugar. No doubt they will cons flavoured candy, and he may have sold it to keepers; but that does not prove they like it b

A. Watki

[22299.]—In answer to "Orderic Vital" (l 22249), candy making is frequently a ticklish I think it is on account of the difference in su and also the neglect of the details in mak With very few exceptions, I have succeeded with both candy and flour cake. The vinegar sh not be used for candy, as it causes the air to ac it and softens, and gets into a sticky mess, and down among the bees, sticking them together, doing more harm than good. Nothing shoul added; but the sugar, when boiled sufficien should be taken off the fire and stirred briskly u it appears to be setting. This prevents recryst ising. When bees are being fed with candy, th require water, and will come out for it if not su plied inside. Some beemasters do this by fountai metal plates, &c., for condensation. I have tried these, so cannot give any opinion.

Chilling brood is subjecting brood to a degree cold that causes them to die, either by allowing much ventilation or by exposing them too l when opening hive, &c. I do not know w temperature is fatal, and I never expose any m than a few minutes *in warm* weather; but I h not seen much of chilled brood in my own stoc Their hatching out when sealed depends on length of the exposure, and the state of the atm sphere. I do not call myself a bee-master, but I a bee-keeper, and very much interested in the pu suit; and I also should like bee matters ventila in "E. M.," but do not feel competent to undert it.

J. I. S

TRICYCLES.

[22300.]—In reply to "Rug" (letter 2225 think, with a little practice, he will be able mount any ordinary hill, if he has a well-m tricycle, in which the position of the rider is o his treadles, as he can then exert a considera backward pressure on the treadle at the end of stroke, which will carry the upper treadle i position for work. "Rug" suggests the tread being placed at right angles, but I think on c sideration that this arrangement would be fou to increase rather than diminish the difficul "Patent 5756," Sept. 1879, describes a tricy driven by opposite treadles and right-angled cra connected by rods, similar to a locomotive, whi renders the machine a good hill-climber.

Old Rug.

COMPOUND ENGINES.

[22301.]—I am obliged to say that I am too b with removing for me to answer "Young En neer" (let. 22278) fully. But as I have already st that with a receiver of 9 or 10 times the size of high-pressure cylinder, the variation in pressu about 1½lb. per sq. in. So that, taking this i consideration, you may calculate the power at y own leisure. Should you adopt a receiver of size to suit yourself, its volume, compared to of the high-pressure cylinder must be found, as by Marriotte's law, the volume and pres are in the inverse ratio, you can readily find pressure at any point, after which the theoret power is a matter of easy calculation.

Dewsbury. **Enginee**

OIL-GAS WORKS.

[22302.]—In letter 22282, p. 451, your co spondent "Os" asks two or three question beg to reply. Oil-gas, made by my retort is l preserved, and used by an ordinary gashold ordinary pressure similarly to coal-gas. A g of oil, petroleum, rosin oil, or other ordinary o melted fat, will yield about 100 cubic feet *good* and some useful brownish tar. Oil-gas ordinarily keep good, and I have, 25 years ag light the Royal Navy, had some compressed atmospheres. Even at two atmospheres press have kept it quite good for four years. No da of back pressure in the vertical pipe of feed-fu if the pipes and ways be clear.

James Copcut

Aylesbury, January 26.

PUMPING BY SUCTION.

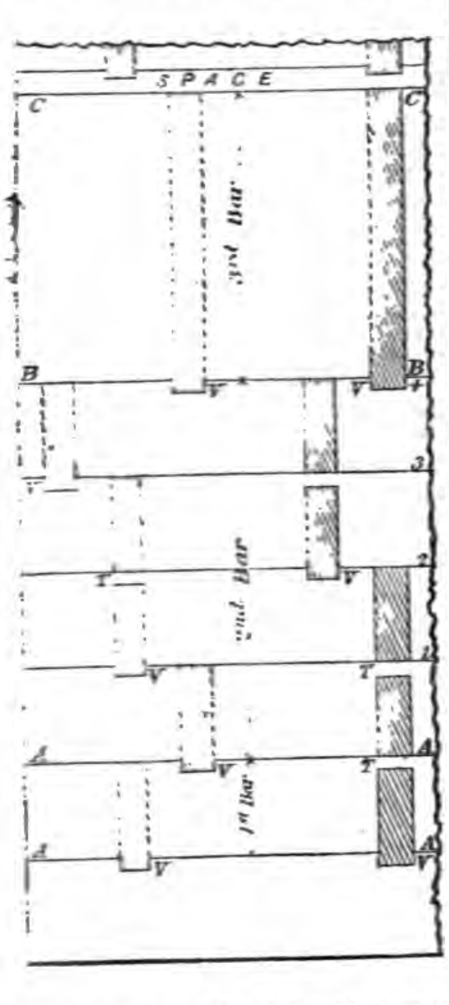
[22303.]—In last week's issue you gave an ex from another paper on p. 453, pretending to s how water can be raised 37ft. by "suction." I deny. I fail to see how a piece of wood with and leather fittings, in whatever form put toge possesses the slightest power to "suck" anyth It seems to me extraordinary that in the 84th of the 19th century there are so few people instrument, containing a set of perforations to test the reeds, and see that they all sound properly.

The next thing is to decide on the length to be taken to represent a minim, which we will assume to be half an inch. Having taken the strip of paper (I use stout smooth drawing or cartridge paper) of sufficient length for the intended tune and about an inch wider than the opening into which it is to be passed, we draw, near one edge, a perfectly true straight line as the basis of operations. Along this line, by means of the scale, are to be marked off the lengths of the bars in the tune, remembering that though no space need be allowed for *ordinary* bars, yet a final bar at the end of a phrase requires a small space to be left, say ⅛in.

Each bar is then to be subdivided into minim, semibreve, or crotchet lengths as required: a semibreve will be 1in., a minim will be ½in., a crotchet ¼in., a dotted minim ¾in., and so on. It is advisable to check this over two or three times, as mistakes will be very apt to occur at this stage. A wrongly cut hole can be stopped up or an omitted hole put in, but a mistake in the position of a bar will spoil the whole tune.

Having thus secured the two divisions, lines should be drawn at each mark right across the whole width of the strip, for which purpose we use the "set square" and "straightedge" to insure the lines being all parallel and all at right angles to the longitudinal line first drawn.

For a beginner the next step had better be to carefully mark off at each end of the paper, by means of the cardboard strip before mentioned, the positions of the lines of holes, marking both sides, and merely the centre of the holes. Then with the "straightedge" the longitudinal lines are drawn in, extending the whole length of the strip. We thus get the strip marked out into oblong spaces all of the same width (that of the holes), but varying in length according to the positions of the cross lines which mark off the bars and the notes.



It is then easy to mark which of these oblong spaces are to be cut out to form the tune. We then go over it again and put in the "bridges" of the repeated notes by shortening the first hole say ⅛in. in each instance; we also add the *extra* length of hole for the reason explained, and for which 1/16in. will suffice. These shortenings and lengthenings of the holes should be boldly marked, to catch the eye in cutting them out, and save carrying the cut too far. After a little practice it will be found unnecessary to draw the whole series of longitudinal lines, and the holes can be marked off at once by the aid of the divided strip of cardboard, and drawn in individually or even cut out at once.

I find a currier's knife with a sharp point is the best to work with, and the wooden block to cut on should be as free from grain as possible, or the knife is apt to follow that instead of the pencil marks. Annexed are a few bars of a hymn tune; but in order to bring it within the width of a column only a part of the width is included in the illustration. In this are shown the divisions into bars, as A, B, C; the subdivision into minims, as 1, 2, 3, 4; and a dotted semibreve occupying the whole of the third bar, with the succeeding narrow space to suit the end of the phrase and produce a pause. The "bridges" marked T, T, T, separate the successive repetitions of the notes, while the *extra* lengths of the perforations extending beyond the lines are seen at V, V, V, &c. For an orguinette, aurephone, &c, the holes would be altogether longer.

I may, perhaps, refer here to my reply to query 52577 on page 453, in order to remark that, speaking generally, and without reference to the question of key characteristics, it is easy to transpose any tune (within the compass of the instrument) so as to suit the scale employed. **A. S. L.**

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[51843.]—**American Railways.**—The principal American railways with total mileage may be given, without any special order, as follows:—New York, Central, and Hudson River Railroad, 700 miles of track, capital stock £18,000,000; New York, Lake Erie, and Western, 1,500 miles, capital stock, £1,500,000; Grand Trunk of Canada, 2,332 miles; Pennsylvania Railroad, 2,047 miles; Baltimore and Ohio Railroad, 1,575 miles; Chicago, Milwaukee, and St. Paul Railroad, 4,465 miles, capital stock £10,000,000; Northern Pacific, 2,900 miles, capital stock £18,000,000; Union Pacific, 4,251 miles, capital stock £12,000,000; Central Pacific, 3,780 miles, capital stock £12,000,000; Chicago and North-Western, 3,552 miles, capital stock, £13,000,000; Chicago, Burlington, and Quincy, 1,960 miles, capital stock, £14,000,000; Wabash, St. Louis, and Pacific, 3,423 miles, capital stock £10,000,000. The querist asks why stocks fluctuate so much. Let me reply by referring to Northern Pacific stocks, which a few months ago were at 45, and have since gone to 22, while the preferred stock has declined from 85 to 50. Within the next six months they are as sure to get to the original figures, as the sun is to rise to-morrow. The explanation is about like this. Henry Villard, who, up to four days ago, was president of the road, was a dashing financier. He took hold of the road when it was incomplete and bankrupt. He borrowed money by millions, and last September the road from St. Paul to the Pacific coast was completed. When his work was done, a syndicate of bankers who had loaned the road a great deal of money instituted a "bear" movement in Wall-street—the money market of New York—and prices began to fall. Once having started on the downward rush, they kept on. People got scared, and they sold out of their stock. Like sheep falling down a precipice they went. The "bear" movement came at an unfortunate time, just when capitalists who might have picked up the falling stock had all they could do to take care of their own belongings. The Northern Pacific railroad runs through one of the finest and most fertile countries on the earth. There is no finer railroad property in the United States. Let me give another illustration as to how railroad property may fluctuate. Jay Gould, one of our great and unscrupulous railroad kings, acts the part of an Ahab to a Naboth. He sees a small railroad that he desires to secure for himself. He can get it without paying its actual value—in this way. We will say that the railroad is called the A. and B. C. railroad. Its stock is selling at 50. He tells a newspaper man that he proposes to run a branch of the D. and E. F. railroad parallel with the A. and B. C. This bit of intelligence makes men thirsty for more, for they know he can do it if he likes. In the meantime the A. and B. C. stock declines to 48. Many stockholders desire to sell if a parallel road is to be started. The newspapers get more "news"; presently it is the talk of the "street." The name of the firm from whom the steel rails have been purchased is given: elaborate articles are written, setting forth what a splendid thing the new line will be to the D. E. and F. road, as a feeder, while the A. and B. C. company will soon become bankrupt. The A. and B. C. stock goes down, in all probability, to 20, and Gould, who never had any intention of building a parallel line, buys all the stock he can. Then the newspapers learn that he has altered his mind, and is not going to build a parallel line, and up goes A. and B. C. stock again to 50. If Gould chooses to hold on to his stock he can; if he sells, he makes a tremendous profit. If my English friends ask whether or not it is wise for them to invest their money in American railways, I answer unhesitatingly in the negative, unless the investor has some special information from a friend who knows. American railways are a lottery to the uninitiated. There are fifty ways of investing money in this country in which large rates of interest are obtainable; but the small holders of railway stocks are in great danger of being badly squeezed by the big men. There is no point where money can be invested to better advantage than right here in Dakota; but a man should come and see what he is doing with his money, unless he has a friend on whom he can rely.—R. M. Tuttle, Mandan, Dakota, U.S.A.

[52256.]—**Brush Dynamo.**—To "W. H. E. Coventry."—I cannot see how my machine can short-circuit itself. I may say, since your reply appeared, I have altered my commutators as you suggested, by replacing my former ones with a proper "Brush"; but the results are not so good. How do you account for this? Formerly I could red-hot my candles, but now not even this will occur, and I must think winding my A. with smaller wire will give better results—say four gauges finer. At present the slightest separation of the candles will break the circuit. Is there any particular mode of placing the commutator plates with respect to the coils? Mine are soldered centrally opposite their own coils on end of wire, and the brushes laid on just as the coils come out of F.M.'s—Williams.

[52302.]—**The Cheapest Food.**—From personal experience in a long course of years as a plate-mill furnaceman, there is nothing to equal dandelion beer with bitters to taste, such as wormwood, gentian, or buckbean, with a little ginger and sugar. Fermented and bottled it is a good, healthy stimulant. The dandelion acts on the liver, and the bitters keep the stomach in good order. 2nd. There is nothing better for free and largely drinking than oatmeal and water. I have seen vast quantities of it used in summer time in the ironworks by men and boys when in the most profuse perspirations, and never saw any ill effects, however large the quantity one drank. It is very refreshing and wholesome, and surely that is all any workman really requires. I am not now connected with the ironworks. As a matter of choice, I invariably have simple water to my midday meal.—T. Taylor.

[52408.]—**Ringworm.**—A very simple remedy for ringworm, and I can vouch for its efficacy, is the application of oil of tar. The way I have applied it is to turn up the bottle containing it, then take out the cork, and gently touch the place affected: two or three applications is usually sufficient, and often one will do. If the patient is a child, its hands should be held for a few minutes while the smarting ceases, and to prevent its rubbing the oil or getting it into the eyes, where it would be painful.—J. Thorp.

[52414.]—**G. W. R. Engines.**—The following are the dimensions of the 4-coupled (trailers) single framed side tanks built at Swindon. Cylinders 16 by 24; boiler, length 10ft. 6in., diameter 4ft; outside firebox, length 5ft. 1in., breadth 4ft. 1⅛in.; inside firebox, length 4ft. 6in., breadth 3ft. 6in.; height 5ft. 6in.; area of firegrate 15·75; 161 tubes 2in. diameter, 14 tubes 1⅝in. diameter (175 tubes total). Heating surface: Firebox, 87 sq. ft.; tubes, 999 sq. ft.; total, 1,086 sq. ft. Diameter of leading wheels, 3ft. 6in.; diameter of coupled wheels, 5ft.; centre of leading to centre of driving wheel, 7ft. 6in.; centre of driving to centre of trailing wheel, 5ft.; extreme length of frame, 25ft. 2in. Tanks hold 790 gallons. Weight of engine in working order. Leading wheels, 9tons; driving wheels, 12tons 2cwt.; trailing wheels, 12tons 2cwt.; total, 33tons 4cwt. These dimensions apply to engines 3-6 (1867), 455-470 (1869), 613-632 (1871), 967-986 (1874), 1401-1420 (1878). All these have domes. Nos. 1445-1452 are slightly larger and have no domes. The cylinders of these are 17 by 24. The side tanks built at Wolverhampton have leading and driving wheels coupled, 5ft. diameter, and cylinders 15 by 24. Some have had cylinders enlarged to 16 by 24. I have no further dimensions of these. The broad gauge goods have 5ft. wheels, and 16 by 24 cylinders. I refer to those built at Swindon about 18—.—Meteor.

[52465.]—**Belt Working off Pulley.**—It appears by "Engineer's, Dewsbury," answer to the above query, that he would have us to believe that his answer is to be final. I think it is hardly fair, "Engineer," until you have tried the case (under consideration) on two perfectly horizontal shafts by bringing the shafts nearer together or further apart, as the case needs. The illustration that you give is a very poor example of belt working off pulley when the shafts are furthest apart. If correspondents would give their advice a little more from practice, it would save a lot of unnecessary space and twaddle. Let me say that I have had two cases of belt working off pulley at the side were nearest together (only this last week)—one

casing raised above barrel outside 2ft. 6in. above centre of boiler. Inside firebox: Length, 7ft. 4in.; width, 3ft. 5in.; height, 5ft. 3½in. (front), 2ft. 3½in. (back). Heating surface: Tubes, 1,084 sq. ft.; firebox, 110 sq. ft.; total, 1,194 sq. ft. 192 tubes, [illegible] diameter, 10ft. 4½in. long. Weight in working order: Leading wheels, 12tons 18cwt.; driving wheels, 13tons 15cwt.; trailing wheels, 12tons; total, 38tons 14cwt. Can any reader say what these engines are numbered?—Meteor.

[52618.]—**Seismometer.**—J. Byatt's query is too general, since the kind of apparatus used will depend on the locality—i.e., on the kind of earthquake shock to be registered, and also on the particular elements of the shock it is desired to record. He should look up *Transactions* of the Seismological Society of Japan, in Vols. III. and IV. of which are described forms of pendulum seismographs. See also *Philosophical Magazine* for Sept. and Nov., 1881. In No. 154, *Quart. Jour. Geological Society* for May, 1883, p. 218, is a short description with diagrams of a seismographic apparatus as used by Messrs. Gray and Milne in Japan. This, which is the most recent form of the apparatus, "is designed to give a complete record of the form, magnitude, direction, frequency, time, and duration of the motions of a point of the earth's surface during an earthquake." The mechanical principles involved in its construction are very elaborate. To do useful work J. Byatt should become acquainted with other observers—see, e.g., "Report of Committee on Earthquake Phenomena." B.A. Report for 1882, p. 205.—F. G. S.

[52623.]—**Mural Decoration.**—My advice is: Get some experienced house painter to prepare the walls and to give them one, or, if necessary, two coats of what they (house painters) call flatting. On this, when dry, you should draw your decorations in white chalk, or, better still, tailor's pipeclay. If you use the former, let it be soft, or it will not mark on the paint. Next come the colours: If you want yours to look like your friend's, you must use colours mixed with turpentine instead of oil. If you use artist's colours, use turpentine only as a medium. I shall be pleased to give any further hints that may be required as your work proceeds, and if you care to advertise your address, I would do so by letter, which would not necessitate your waiting a week.—Edwd. Flowerday.

[52623.]—**Mural Decoration.**—As no person has yet suggested that the colour for the wall which was laid on by Italian workmen in her friend's house, might have been mixed in with the plaster on the wall, I may be pardoned for occupying space on the subject. A celebrated London artist was among the first to use plaster which was coloured before being applied to the wall. I think it was Sir Frederick Leighton. I saw it mentioned in a recent number of *Harper's Magazine*. I could not, however, see how this decorating could be done by an amateur, especially a lady one; as, beyond the physical power, a considerable experience would be required as to the permanency of the colour, and how far it would withstand the action of the lime.—A. Howland.

[52623.]—**Mural Decoration.**—I am much obliged to "Os" for his kind interest in my intended work, and for his mention of "flatting," which is, no doubt, the material I require. Since Mr. Lancaster's reply to my questions I have obtained an excellent little book, entitled "The Paperhanger's, Painter's, Grainer's, and Decorator's Assistant," containing much information, given in a practical style. I have, I think, decided to work in paint, not in distemper, on account of the greater durability of the former, although I have now learnt from a house painter the proper mixture for distemper to render it sufficiently firm, even when rubbed or cleaned. "T. B. C." will have discovered, from my hint to Mr. Lancaster that, as Dickens puts it, I am "deprived, by the wrongs of my sex," from the possession of that domestic treasure which the wise man tells us, "whoso findeth, findeth a good thing." I have, therefore, to be content with a husband, and, as we must not encroach upon the valuable space of the Mechanic's pages with discussions as to the sentiments of "our sisters, our cousins, and our aunts," I will only add that he, perhaps, from having known me undertake a few previous things rather beyond the pale of ordinary woman's work, and get through them, does not seem so hopeless as to the realisation of my project as "T. B. C." appears to be.—E. C. N.

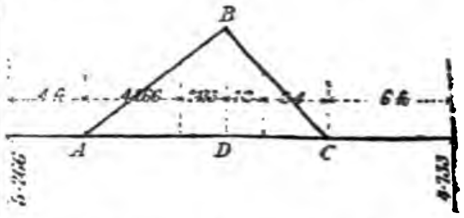
[52623.]—**Mural Decoration.**—Our fair correspondent wishes to know "if, after I have painted my wall over with a coat of distemper, I can paint the design over it without further preparation": I am not quite prepared to answer this question in the affirmative because of the supposition that "E. C. N." intends to paint in oils. Distemper grounds absorb the oils, and consequently the colours will not blend. The effect would be similar to writing in ink on a piece of fresh-planed wood. Therefore I should not like to advise in this point, which is almost certain to end in failure. If, however, instead of the painting in distemper is resorted to, the walls will only need a first preparation of being thoroughly cleaned, and then, secondly, washed over with a colour-wash of a delicate pink salmon tint. This will, perhaps, give more repose as a background than either a pale grey or drab, as some portion of the background must appear. The colour-wash being first properly prepared, size, well melted, must be added to it, in the proportion of, say, four pounds weight to each pailful of colour-wash. This, if properly done, ought to make a firm ground, which does not hereafter rub off. In painting in distemper the colours must be prepared to obtain the like result; that is, if it is necessary to add so much size to the colour-wash to prevent it coming off on the clothes (like chalk or whiting), the colours must be mixed with a like preparation; but, as in the operation of painting the size will dry, perhaps, too quickly, in that case the colours might with advantage be mixed with clean flour paste of a consistency which will enable them to work freely from the brush. But mural decoration of this kind is an art, and can only be acquired by practice to insure success. Under any circumstances, the undertaking in the hands of an amateur will, and must be, attended with many disadvantages. In the first place, granting that everything was truly and properly prepared as directed, the painting, when done, would last only so long as the animal or vegetable substances which bind it withstand the action of the atmosphere; consequently, in our moist climate (winter especially) it would get somewhat deteriorated in perhaps three or four years at most. Oil painting is different; but that, to be effective, cannot (as already observed) be executed on distemper ground without absorbing the oils, and thus preventing the proper blending of the tints. As "E. C. N." explains it, it is very clearly seen why her friend's drawing room "looks dull"; but I am not in the secret of the remaining process, unless the colours have been mixed with the white and yelk of eggs (the former for all light colours and the latter for the darks); this, when dry, would form with the lime a size that is insoluble. I see another contributor ("T. B. C.") has replied to this query. I fully endorse all he says; as to his "pale grey" ground, all that greatly depends upon the subject to be executed, and no definite rule can be laid down. As to colours, I know of no particular work which treats upon this subject fully (an art we should call it); however, in the choice of colours care must be taken to confine them to those that lime will not deteriorate, and which also will not be altered by the action of light. If "E. C. N." prepares her own colours, they can be obtained in the crude state at any oil-colour shops; but I am mistaken if they will not require much time in their manipulation. I append a list of colours likely to be useful. As an amateur, I would not advise "E. C. N." painting her walls in oils without first trying her skill elsewhere on a smaller scale. *Colours for Distemper Painting.*—For Whites: Chalk and lime to be used. The latter hardly advisable perhaps, on account of the preparation required to make it available as a vehicle. For Black: Soft black chalk, or charcoal black. Lamp black is most intense. For Yellows: Naples yellow, Indian yellow, gamboge. The different yellow lakes; but many of these are not so permanent if exposed to a strong light. The Reds: Carmine (not permanent), cinnabar (or vermilion), metallic; it might be acted upon by the lime. The Lakes: Indian lake, scarlet, and crimson do. Brown pink (one of the yellow lakes), a vegetable colour. Madder lake (red colour): This may be acted upon in two ways to form other colours. First—it may be changed into a dull orange by the action of alum. Secondly—to an orange yellow by the action of hydrochloric acid. The Earth Ochres: Yellow ochre, &c. The Umbers: Light and brown. The purples obtained of various tints by the admixture of reds and blues. The Blues: Prussian blue, ultramarine, smalt; but I know very little of this latter colour. The Greens: Most of these are metallic; but may be formed by the mixtures of the yellows with blue. The Browns: Bitumen, asphaltum. Prussian blue, if heated to an intensity towards redness, will produce two or three shades of colour (varying to the degree of heat obtained), from yellow ochre to dark ochre and black. A good brown can be obtained by burning whalebone to a fine powder, and then levigating it.—Geo. H. Lancaster.

[illegible]—**Varicose Veins.**—With all respect to "E. W. ...," I still recommend to "Poor Sufferer" the bandage described. The fact is, while "E. W. ..." has been reading his book, I have been wearing the bandage, and, since September, as neither gangrene has set in nor my leg has rotted off, but is in a more healthy state than before, the question solvitur ambulando. I have also worn Martin's bandage, but rejected it because the skin secretions did not escape, and my leg showed a tendency to break out in ulcers. Of the two, Martin's bandage is much the more powerful, and less easy to apply; its advantage is in its cleanliness. The bandage I described no doubt may be used as described by Dr. [illegible] or one of a different kind may be referred to; but the one I mean is nothing more than a long length of elastic brace material, and need not be applied to produce more than a gentle pressure; and practice and perseverance are not necessary to apply it. For comfort, I strongly recommend the one I have mentioned, and having used both, I can speak to facts within my own experience. Don't be frightened, "Poor Sufferer."—H. P.

[52653.]—**Electrical Currents.**—I think "Antares" will allow that his water analogy is correct when he considers what would be the relative effect if he were to place his hand in a large volume of water with 3ft. head, and then in the way of a small stream falling from 30ft. Cannot he see that the first case is the low potential current carrying a large amount of energy along in a mild way, and the second is the same amount of power used to propel a small quantity of energy at high speed? With respect to the destructive nature of high-tension currents, the force of the water falling on his hand from 30ft. above would soon convince him that the same power can be expended in different ways. By the way, in my note of last week read "presence" for "pressure" of magnitudes. The last extract from the Blue Book probably only refers to those cases where a constant E.M.F. is maintained. Registration of this would be effected separately. I fail to see what are the two applications of the word "volt"—it only represents the E.M.F. of the "body," or "quantity," or "current" of electricity which is passing in a conductor; or, in other words, the height from which it is falling.—Cosmos.

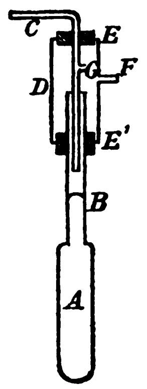
[52654.]—**Point of Greatest Transverse Strain on Girder.**—I am sorry you should have been put to the expense of engraving a block for the reply given by "Palmer, Accrington," as it is no solution at all of the problem. I have worked it out myself by calculating the strains in "foot-tons" at several points, plotting these as ordinates, and so obtaining a curve of strain with an approximate maximum; but the method is both troublesome and tedious, and I much wish to obtain something less complex, and if possible more exact. Where are our mathematical correspondents?—Querist.

[52654.]—**Point of Greatest Transverse Strain.**—The pressure on each bearing will be inversely as their distances from the centre of gravity of the load, 5·266 tons and 4·733 tons. The moment of the force tending to break the beam at A is 5·266 tons × 4ft. The moment of the force tending to break the beam at C is 4·733 tons × 6ft.; at D it is 5·266 tons × 10·4ft., less the weight of A D B = 6·4 tons × 2·133ft., the distance of its centre of gravity from line B D, or 4·733 tons × 9·6ft., less the weight of B D C = 3·6 tons × 1·2ft., the distance of its centre of gravity from line B D. At any point between A and D it is 5·266 tons × its distance from the point, less the weight of the load to the left of the point × the distance of its centre of gravity from the vertical line through the point. And similarly for any point between C and D it is 4·733 tons × &c. But with right instead of left, then, if the results of these calculations at a sufficient number of points are set off to scale on vertical line drawn at the points, a curve drawn through the top ends of these lines will show the ratios of strains at any point, and where the curve is highest will be the point of greatest strain. From the top of the line at A to the left-hand bearing, and from the top of the line at C to the right-hand bearing, the line showing the ratios will be straight. What the actual strains are depends on the section of the beam, which is not given. "Querist" should attend classes or read on "mechanics" in order to do these questions for himself.—J. S. C.



[52664.]—**G.N. Engines.**—I do not think engine No. 70, having outside bearings, is a new one, as engines with outside bearings have not been built for the G.N. since 1866. I do not know No. [illegible]; but if it is a "mixed" engine it will be like 67 and 68. No. 67 has 6ft. coupled leading and driving wheels, and 17½in. by 24in. cylinders. Both 67 and 68 are rebuilt engines. The springs of these engines are underhung from the outside frame.—Meteor.

[illegible]—**Continuous Temperature.**—A small apparatus, known under the name of "thermostat," is capable of obtaining the desired effect. It can be made of glass by anyone a little experienced in the art of glassblowing, or it may be obtained at a trifling cost from Cetti's or any other glassblowers. Its construction may be easily understood by the accompanying diagram. A is a



good-sized bulb containing mercury; G represents the tube connected with gas supply. It enters the tube B, and may be inserted into the latter to variable depths by means of the connecting tube D, and the airtight corks E and E'. F is the tube which connects the thermostat with the heating burner. G is a pinhole, blown or bored into the tube G. The manner of using this instrument is as follows:—Connect G with gas supply, and F with the burner by long flexible indiarubber tubes. Plunge A into the liquid, which is to be kept at a constant temperature, and fix the instrument in an upright position. Heat the liquid by applying the burner; when the desired temperature is obtained, push G into B until it just reaches the surface of the mercury. By this means the gas is almost entirely shut off, G only remaining for its passage into the burner; the result will be a very small flame, insufficient to keep up the temperature of the liquid. When the latter cools down the mercury contracts in A, and the passage of the gas becomes enlarged; this goes on until an equilibrium is reached, which allows just enough gas to reach the burner to keep the temperature as required. By means of this apparatus I have kept constant temperatures, varying within 1° C. for days and weeks.—Organic Chemist.

[52691.]—**Assaying.**—It is usual to add 16 lead for 1 copper, and that will be sufficient. A cupel that weighs a little more than the lead to be cupelled will be large enough.—Augustus.

[52692.]—**Cleaning Sponge Cloths.**—In reply to "Engine Shed's" inquiry, there are several methods of effecting this. I do not knew the exact method adopted at Crewe; but the cheapest and simplest way is to make an alkaline solution of the usual washing kind—i.e., by boiling lime and the alkali of commerce (50 or 52 per cent.) together in a steam-jacketed or other vessel for 2 or 3 hours, stirring frequently till well dissolved; draw off the mother liquor to a settling tank or tanks, reserving the settlings of the boiling tank for use in the next boiling. The mother liquor ready for use is generally tested by the ordinary Twaddell hydrometer (which can be obtained at any scientific instrument shop). It is best to make a good strong mother liquor, not less than 20° Twaddell, so that the washing liquor can be regulated, more especially if the cloths are very dirty and mineral oils have come in contact with them. The cloths being transferred to the boilers (I prefer jacket boilers) are allowed to soak in tepid water a short while, and then the washing liquor is turned on in the proportion of two gallons of mother liquor to one gallon of water. These proportions of both water and liquor. however, can be regulated and made weaker or stronger, according to the condition of the cloths. They are then boiled an hour or more, and the cloths turned over occasionally to let the grease escape from the mass; the foreman can easily satisfy himself as to when the cloths have been boiled long enough, and the grease saponified, by taking a cloth out and washing by hand in a pail by means of hot and cold water. I do not advocate too many cloths being boiled at a time; if too many are thrown in they form a dead, solid, adhering mass, making it difficult for complete separation of the grease. A moderate quantity will be done in one-third the time, and most effectually turned over and cleansed. After transferring from the boilers to the ordinary washing and heating engine, where they must be well washed in a plentiful supply of water, the cloths are then "hose-piped," or, what is better, are thrown into a centrifugal drying fan (in use, I believe, at Crewe—the maker's name I have forgotten). During the rapid motion of the fan a jet of cold water is made play on the cloths, which is continued till nothing but clear water runs from the discharge pipe at the foot of the fan. It is best not to fill the revolving fan too full of cloths, as this process can be completed in a few minutes, and can be repeated often with plenty of water. The transfer of the cloths to the usual drying room completes the cleansing. The grease rising to the surface in the boiling pans is ladled into tanks, or is best run down into a tank below the level of the floor. In doing a quantity, it is important to see that the process is regular and rapid, and that they are turned well over in the boilers, so that the grease rises in a good scum. In the washing and heating engine give the cloths plenty of water.—Chemicus.

[52713.]—**M.R. Engines.**—To "Historian, M.I.M.E."—The Midland Railway Company have decided to adopt the red colour now to be seen upon some of their engines. The paint is not only cheaper, but is said to be more durable. A trial has been made, in which engines painted green and red about the same time were examined two years afterwards. The result was said to be much in favour of the red colour, which is therefore to be adopted.—Meteor.

[52716.]—**Lathe.**—With the assistance of these sketches I think you will find no difficulty in making the pattern you require. If you should meet with any hitch, call again. But it is not a case of "arms and other parts to casting of headstock," but of a headstock of a different type, and differently proportioned to that which I have described. Back-gearing and screwcutting additions mean a heavier casting, and properly, cone bearings; also they mean a wider space between the uprights to take the gear wheels, and then, in addition to these, the arms for the back spindle. Figs. 1, 2, and 3 give views of a headstock such as you require. The width between, 7¼in. or 7in. between facings, is made to take a three-speed belt pulley of 3in., 4½in., and 6in. diameters respectively, each of 1½in. thickness, and gear wheels 1in. thick. If you choose instead to have a gut or a rope pulley, you can narrow the width space a little. The gear wheels are of 18 and 54 teeth respectively, giving power of 9 to 1, and the centres of their bearings are 4⅜in. apart. In making the pattern you can set to work, and frame together just as described in the first article on "Cheap Lathe," p. 165, joint, dowell, &c., working, of course, to the new dimensions. Don't, however, cut the arms for the back gear out of a piece with the sides, else you get short grain. Put those arms on with a stump tenon in the manner shown on Fig. 4, glueing the hollow in afterwards (Fig. 5, *a*). The facings for the mandrel bearings being in the *joint* are fastened on, together with their prints (Fig. 6, *a*, *a*), that is, if you choose to cast the holes in, though leaving them to be drilled insures a sounder casting in a small lathe. But the bosses for the *back* spindle are wired on Fig. 6, *b*, *b*, where they are shown slid back a little on their wires. You must allow all these boss facings ¼in. thick in the pattern, so that you may have something to face off the casting. The arrangement for the back centre is as follows:—The mandrel passes through both

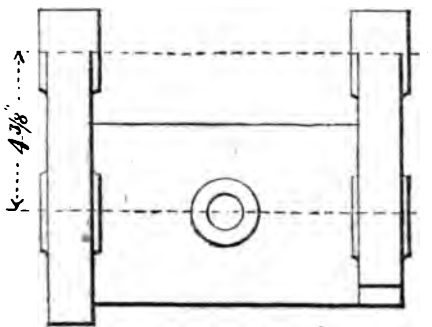


Fig. 1. Plan.

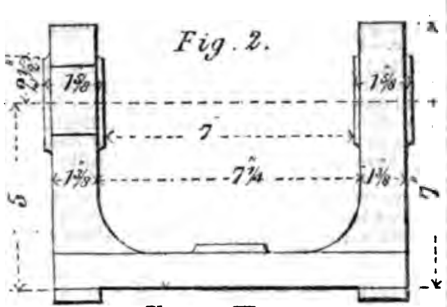

Fig. 2.

Front Elevation.

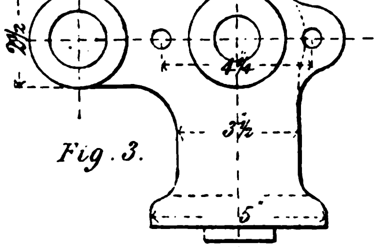

Fig. 3.

Back View.

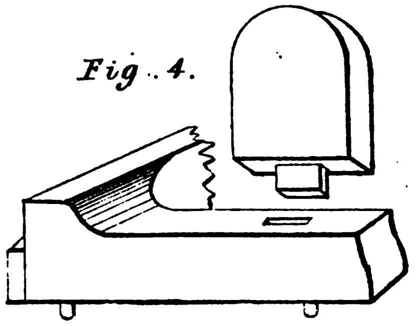

Fig. 4.

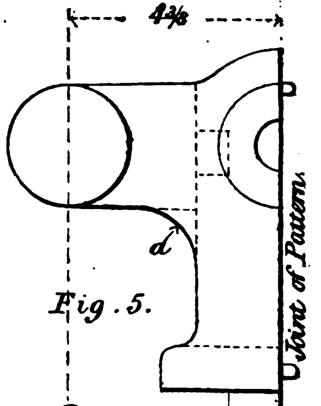

Fig. 5.

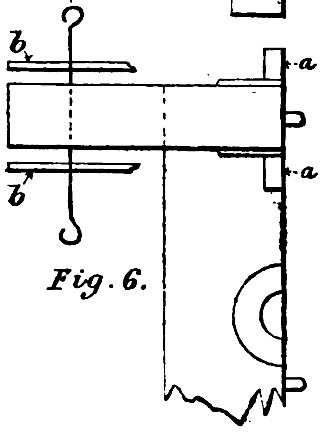

Fig. 6.

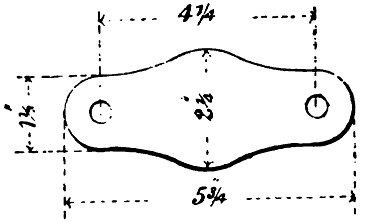

Fig. 7.

ends of the headstock, and is prolonged about 3in. beyond the tail end to carry the first cog-wheel of the screw-cutting train. A bridge, Fig. 7, is cast, and maintained, say, at a distance of 4in. from the back of the headstock casting by means of distance pieces, the centres of which are given at Figs. 3 and 7. Then the actual dead centre passes through the middle of this bridge, and is held, as before, with adjusting nuts. You must make the poppet pattern heavier also for a back-geared lathe than for one intended for hand-turning. The design may remain as it is at present; but I should make the mandrel 1¼in., instead of ⅝in., and add ¼in. to all thicknesses of metal. Driving-wheel, of course, is altered; crank should be double; heavy flywheel is necessary. A 5in. back-geared, screw-cutting lathe is a very different thing from a 5in. cheap wood or plain metal-turning lathe, and requires a high degree of manipulative skill and good appliances to construct successfully.—J. H.

[52718.]—**Dog Poisoning.**—"M. C. H." will find sulphuretted hydrogen in its concentrated form a very quick and powerful poison. Obtain about 1lb. of iron sulphide and put it into a large beaker, pour some hydrochloric acid, diluted with its own bulk of water, over it; cover with a glass plate and wait until the beaker is well-filled with the gas. Remove the glass plate and dip the nose of the animal into the gas. It will die instantaneously. It is hardly necessary to caution against inhaling any of the concentrated gas one's self. It is also absolutely necessary to perform the operations in the open air.—Organic Chemist.

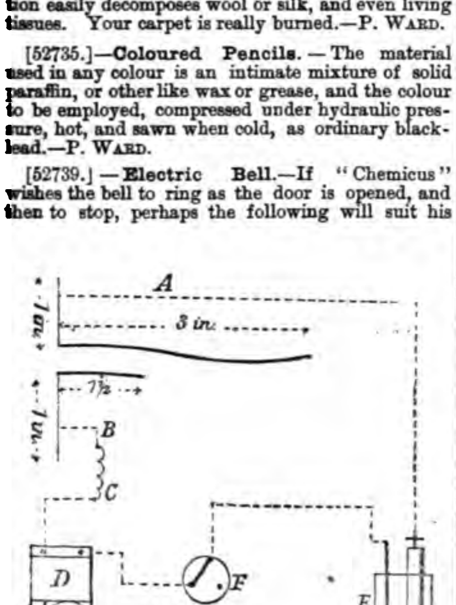
[52727.]—**Quantity of Water Used.**—I think Mr. Webber will find the following answer his purpose:—$2\frac{1}{2} \times D^2 \times \sqrt{P} \times 6\frac{1}{4} \times 60$. For 40lb. press. $= 2\frac{1}{2} \times \cdot375 \times \cdot375 \times 6\cdot32 = 2\cdot22185$ cub. ft. per min. Then $2\cdot22185 \times 6\cdot25 = 13\cdot8865$ galls. per min., and $13\cdot8865 \times 60 = 833$ gall, per hour. For 60lb. press. $= 2\frac{1}{2} \times \cdot375 \times \cdot375 \times 7\cdot74 = 2\cdot721$ cub. ft. per min.; then $2\cdot721 \times 6\cdot25 = 17\cdot00625$ galls. per min., and $17\cdot006 \times 60 = 1{,}020$ galls. per hour.—Wm. Routledge.

[52731.]—**Axle of Electrical Plate Machine.**—I have a machine with plate same size as "W. H. H.'s," only not quite such thick glass. My axle is made of oak, and the hole is ¾in. diam. I first cut circular pieces of chamois leather to fit caps, with the hole cut in the middle, and fixed them on to each with "Giant cement," and when perfectly dry fixed the cap on to the glass plate. I got the caps turned so as to fit tight on to the axle. The cement when set is a kind of thin layer of jelly, so that when the machine is put before the fire it allows the glass to expand, and does not crack, as one did which I made with glue. I have got from 1½in. to 2in. with my machine.—Plate Machine.

[52732.]—**Permanganate in Carpet.**—I am afraid you will never remove your stain so long as it is a carpet. The permanganate in a strong solution easily decomposes wool or silk, and even living tissues. Your carpet is really burned.—P. Ward.

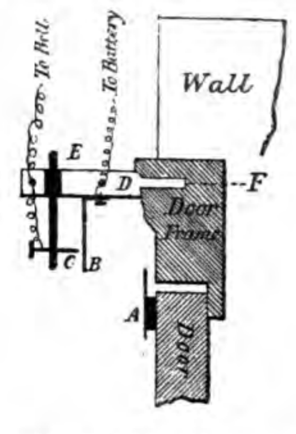
[52735.]—**Coloured Pencils.**—The material used in any colour is an intimate mixture of solid paraffin, or other like wax or grease, and the colour to be employed, compressed under hydraulic pressure, hot, and sawn when cold, as ordinary black-lead.—P. Ward.

[52739.]—**Electric Bell.**—If "Chemicus" wishes the bell to ring as the door is opened, and then to stop, perhaps the following will suit his purpose:—A is a spring of hard brass about 1-16in. thick and 1in. wide, fixed on to architrave moulding of door frame; B is a similar spring fixed on to door, the connections are shown in sketch; C being short helix where the door hinges, to prevent the wire breaking; D, the bell; E, battery; F, switch to cut off when not wanted.—Practice.



[52739.]—**Electric Bell.**—It would be of advantage if "Os" would only bear in mind the excellent advice given weekly "to write what he knows, and as much as he knows, but no more"?—*vide* his reply to "Chemicus," pp. 541. Could much greater nonsense be written, seeing that every bell-fitter knows the thing to be done is one of the simplest things in the trade, the "apparatus" costing about 2s., and being in common use on shop and area doors without number. He seems to have heard of the merits of Leclanché's battery, but the fact that in its best form (as in use for the last four or five years), it is made without a porous cell, is apparently unknown to him, and so he dogmatises and misleads.—One Jealous of the Credit of "Ours."

[52739.]—**Electric Bell.**—A is a piece of wood or metal screwed on to door. D is made of wooden bar let in to the door frame at top right-hand corner, supports (E) a wooden rod which carries the brass screw (C). B is a piece of watch or small clock spring bent, and then hardened at a right angle; a hole is drilled (or punched) while soft, and the spring, well brightened, is screwed on to the block as shown. When the door is opened, A presses the spring B against the screw C, and when returning to its place A presses B away from C. Thus the bell will only ring when door is being opened. The block may be 6in. long, and A may be made of steel spring, which gives longer contact. I should advise use of new Leclanché battery; but why not use porous cell?—Cosmos.



[52747.]—**Electric Microscope.**—This is evidently a contradistinction to the oxyhydrogen microscope, such as used to be shown at the Polytechnic.—P. Ward.

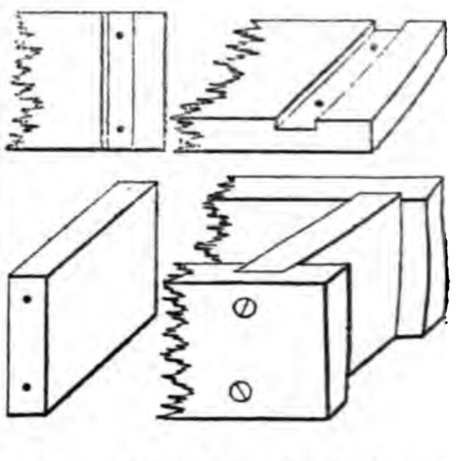
[52751.]—**Recovering Silver.**—Pour some concentrated nitric acid on the electroplated iron. It will dissolve the silver, leaving the iron intact. When the operation is finished, pour the liquid off, and dilute with water; add a solution of common salt. Silver chloride will settle as a bulky precipitate, which must be filtered and well washed. Remove the silver chloride from the filter, put it in a porcelain dish, and add a few cuttings of sheet zinc and a little water, and allow to stand for a week or two. The silver will then be reduced, forming a heavy grey powder. Remove what remains of the zinc, wash well, and melt in a crucible, adding some sodium carbonate as a flux.—Organic Chemist.

[52751.]—**Recovering Silver.**—Procure an earthenware pan (of course the size is determined by the quantity of stuff to be recovered), and into it empty the pieces of iron till about three-quarters full. Cover them with concentrated nitric acid, and gently warm. As soon as all effervescence is finished, the pieces may be fished out, and replaced by others. This goes on till the effervescence becomes slight; the pieces of iron being washed, and the washings added to the main quantity of acid. Muriatic acid is now added, until no further white precipitate is thrown down, at which point the whole is heated and allowed to stand for some time; the clear liquid is decanted off, and the precipitate thrown into a thick calico bag, and well washed with hot water and dried. Mix the dried mass with carbonate of soda and fuse in an earthen crucible, when the silver will be found at the bottom.—D. Williams.

[52753.]—**Copper Ores.**—Weigh out about 5grm. into a porcelain crucible, and heat for about 10 minutes, to oxidise sulphur. Transfer to a porcelain basin, add HNO_3 and H_2SO_4, heat till copper is dissolved, evaporate down to a small bulk, to get rid of HNO_3, add a small quantity of water, and filter into a platinum basin, or small beaker, washing the filter paper 2 or 3 times with water. A quart Daniell battery is about the best to use. It consists of a cylinder of copper, in a solution of sulphate of copper (concentrated), in the centre of which is placed a porous jar containing a rod of zinc, in dilute sulphuric acid. If the ore has been filtered into a platinum basin, connect the zinc pole of the battery so that it touches the outside of the basin, and the copper pole connect to a platinum wire, and allow it to just dip into the liquid. Put away for about 6 or 8 hours, when it will be found that the copper will be precipitated into the basin, and should show its characteristic red colour. The liquor, which should be perfectly free from copper, is emptied out, and the basin washed two or three times with distilled water, and finally with a small quantity of alcohol, after which it may be dried and weighed—the basin being of course weighed before the operation was commenced. If the liquor has been filtered into a beaker, bend a piece of platinum foil (weighed) into a cylinder, and connect with the zinc pole, and allow a platinum wire from the other pole to dip into the centre, when the copper will be deposited on the cylinder.—D. Williams.

[52754.]—**Japanese Scintellelles.**—The compo. for the above is very simple and cheap: it is a mixture of sulphur, nitre, and lamp black (all commercial quality). I have not the proportions really to hand, but the querist can try for himself, putting sulphur most, and so on. But he will find that it is a very nice point to get it right, as I know to my cost. A grain or two, more or less, of lamp-black will make all the difference in an ounce of compo. Put about 3gr. of successful compo. in tissue paper, V-shaped, 4in. long and 1in. at base and twist up.—P. Ward.

[52755.]—**Lathe Bed.**—Certainly you can cut out the gap in the pattern, in which case your print *a a*, Fig. 1, on page 326, must be cut off flush with the bridges that bound the gap, and the core box, Fig. 5, omitted altogether. It seems strange to me that a moulder should object to cores, since they save him a deal of trouble, and minimise the risk of "wasters." However, it is no good to cut up rough; we have to humour these gentlemen sometimes, much against our will. Dresden is not Berlin or Manchester, so you must do as they do in Dresden. The core boxes open by drawing the sides away from the ends, said sides being secured to ends during ramming up by means of screws. See annexed figures, which represent one end of a core box screwed up, and same end taken apart. The rebated grooves may be ⅛in. or ¼in. deep.—J. H.



[52763.]—**Violin Measurement.**—"Otto on the Violin," Cocks and Co., New Burlington-street, will give R. G. Price the measurements of violins, and a description of the old Cremona instruments.—E. E.

[52763.]—**Violin Measurement.**—I would refer you to Mr. Davidson's work on the violin, and a more recent work on the violin, by Mr. Fleming, published at the *Bazaar* office. These contain the mystery so far as known, and also the history of the violin.—A. Howland.

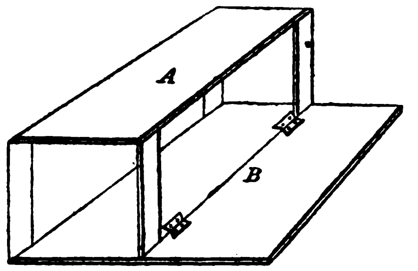
[52765.]—**Preventing Sparks in Contacts.**—"Cowper" will find that if he attaches a small condenser (made of about six sheets of tinfoil 4in. by 6in.) to each side of his contacts, he will not be troubled by what is really the "extra current" eating up his platinum; or he may use a copper or brass wire pin dipping into mercury, and dispense with condenser.—P. Ward.

[52765.]—**Sparking in Contact Breakers.**—Use one of following methods:—1. Shunt your electro-magnet with very fine high-resistance wire, winding the shunt half right-hand and half left-handed, making it at least 40 times the resistance of the electro-magnet. 2. Use a small condenser ¼ microfarad between the terminals of your electro-magnet. 3. Add a large resistance to circuit, and increase battery power till current is same as before. Cosmos.

[52765.]—**Prevention against Sparking in Electrical Contact Breakers.**—I have to thank

"Sigma" for his suggestions in this week's English Mechanic as to prevention of sparking; but one point is not clear to me. He says: "Wind outside the magnet coils another circuit of high resistance, with its ends soldered to those of the magnet wire as a shunt." Let me ask if he means that the outside wire of the resistance coil is to be soldered to the outside magnet coil wire, and the inside wires of the two coils to be similarly connected? Or does he mean that the two ends of the resistance wire shall be joined, say, to either of the outer or inner wires in such a manner that the current passes before (or after, as the case may be) it traverses the magnet coil? If the latter mode of connection, cannot the resistance coil be so arranged as to be quite near the battery, instead of being wound round the magnet coils, as in my apparatus I have eight electro-magnets and eight breakers—only working, however, one at a time. I am, therefore, anxious, if possible, in order to save trouble and expense, that one resistance coil should serve to prevent the sparking in the whole of the circuits. Would "Sigma" kindly insert a small diagram explaining mode of connection in next issue? As for Mr. Bennett's suggestion, that there must be something wrong with my platinum, I think if he uses a current with E.M.F. of 10 volts 2 ampères, with two or three ohms external resistance, he will find a considerable spark on breaking the circuit, with any quantity of platinum.—Cowper.

[52766.]—**Magic Lanterns.**—The best position for oil or oxy-calcium lamp lanterns, giving most of the advantages of a biunial, is obtained by using a stand as below, A and B being the position of the lanterns. It may be made to fold up if thought desirable. The distance between the two tables is just sufficient to allow slides to pass under the upper one; the lanterns may be manipulated from one side, which is a great advantage.—A. B. Cotton.



[52778.]—**Registration of Slides.**—*Perfect* registration can be effected only by having side stops on the left-hand side of the lanterns, and by adjusting the lower and left-hand side of every carrier with the smoothing plane, or slips of wood glued on, as need may require, until with previous registration of lanterns a dead shot is obtained. A good makeshift, and perhaps a better plan for chromatropes, as the handle may then project either side, is a central saw-cut groove, ⅛in. wide and deep, across the lower edge of carrier, which engages a pin, a fixture, also central and projecting slightly above the bed on which the carrier when in position rests. The carrier drops readily into its place, and for most purposes this plan answers well. If "Fred" wishes for it, I can send him patterns of home-made carrier, which all who have tried it prefer to any other. Either side of unframed slide is centred and released with absolute certainty, and perfect ease.—A. B. Cotton, Hartly, Alton, Hants.

[52780.]—**Bath Heater.**—W. B. Bousfield states that he has fitted a number of baths to heat 45 gallons from 60° to upwards of 90° in 4 to 7 minutes. Our water is always between 40° and 50° in winter, and we want it at 98° or thereabouts. This, in proportion, will reduce the 45 gallons to about 25. He states that the cost of gas is about 2d. for each bath. Taking the gas at 3s. 4d. per 1,000, this means 50 cubic feet, which, if burnt in 4 minutes, requires a supply of 750 cubic feet per hour to the burner. This would require a 120-light meter and, say, a 3in. service main. Not many people would go to the expense of a special main, a meter large enough for a factory, and other things in proportion, simply to heat a bath in 4 minutes. We have a 60-light meter and a 2in. service, and cannot get at most over 300ft. per hour = 20 cubic feet in 4 minutes—less than half what W. Bousfield states to be necessary. No doubt what he states is possible; but for one who would go to such an expense there are thousands who certainly would not.—An Old Subscriber.

[52781.]—**Battery for Lamp.**—"Sigma" seems rather to misunderstand my query. I was not seeking information as to the cost, for I shall probably find that out myself. If "Sigma" will compare my letter, No. 52781, with that of "Presto et Presto" and "E. F. F.," No. 50290, in the issue of May 11th, 1883, he will probably notice the difference in the times that our respective batteries continue in action. "Presto et Presto" says, "I find that my battery requires recharging every six or eight weeks." Now here's the rub, for mine requires recharging every six or eight hours, instead of weeks. If "Presto et Presto" and "E. F. F." are still subscribers I should like to hear their opinion on the subject. Now, supposing I were to enlarge my jars from 6in. to 10in., should I get a light for a greater length of time? There is also another wrinkle I should like. I notice that after the battery has been in action about four hours, and I lift out one of the zincs, I find it covered with a thick deposit very much like mud; the liquid in the porous jars also becomes the same colour as that in the outer jars. What is the cause of this? Is it owing to the muriatic acid which I put into the porous jar, or is it the solution in the outer jar that finds its way through the porous pot?—Robert S. Hargreaves.

[52783.]—**Phenylendiamine.**—To separate any of the three phenylen diamines from tin, precipitate the latter with sulphuretted hydrogen. Iron or zinc chlorides may be removed by adding milk of lime or baryta water, and filtering; or they may be precipitated by sodium carbonate.—Organic Chemist.

[52792.]—**Steam Launch.**—How will this do? A A A in Fig. 1 is the stem, keel, and shaft post, B is the rudder post; all three are mortised in the keel; stem, 4ft. long, 4in. broad, and 2in. thick; shaft post, 3ft. 6in. long, 5in. broad, 2in. thick; except where propeller goes through, it must be left thick enough to allow a hole large enough for bush and gland; J is shaft with flange to connect to engine, which should not be less than 1½in. thick; rudder post 3ft. 7in. long, 3in. broad and 2in. thick, which is shown in Fig. 2, marked 5. It will be seen rudder post is made narrow behind where broad mark is shown, to allow rudder to move freely from side to side. H H are small eyebolts for rudder to hook on; F is rudder, 12in. broad and 1in. thick, of any hard wood; 4 is shaft post, with tenon at bottom, for mortising in keel, and bush in with gland studs, for nuts to screw on to nip gland up for packing; 11 is hard wood board, 1in. thick, about 12in. long, to fit on rudder head to steer with; 1 shows top view of boat; V shows shaft-post just level with short piece of deck; R is rudder head, which must stand 6in. higher; 9 and 10 is cast-iron bush and gland; *c c* are two pieces of hard wood spiked on keel, and to stem and shaft post, for strength; those marked D are the ribs, 1in. broad by 3¼ thick—can be ash, but American elm is best: it is a very tough and stringy wood, and not liable to break when bending; 6 and 7 in Fig. 2 will show about what shape the ribs look at each end of boat and the middle; 8 8 are bits of inch board, edge up, fitted in boat bottom for floor to nail to—about twelve of them; the broad mark down stem, shaft post, and along keel is a groove nearly V shape; K will show the groove—it shows the end view of keel. The bits at each end of keel must not be cut off until after the mortising is finished and post driven in. Keel is 20ft. long, there is 8in. of space between shaft and rudder post for propeller to work in, so shaft will have to be drawn back a bit to allow propeller to go on, Propeller should be about 24in. diameter; 2, in Fig. 2, shows the first plank that must go on, which is nailed to the groove in the keel; then all the rest will be shape of the 2 board marked, 3 showing how they lap over each other about 1in. The planks should be elm, if you could afford it: white wood will do, but not near so well—they will be liable to split when springing them in their place, and nailing them on. The nail is wrought iron, with small washers with them, made on purpose for boats.

Fig. 1.

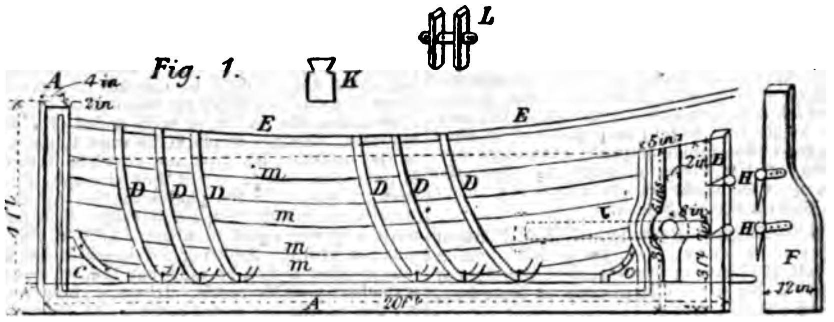


Fig. 2.

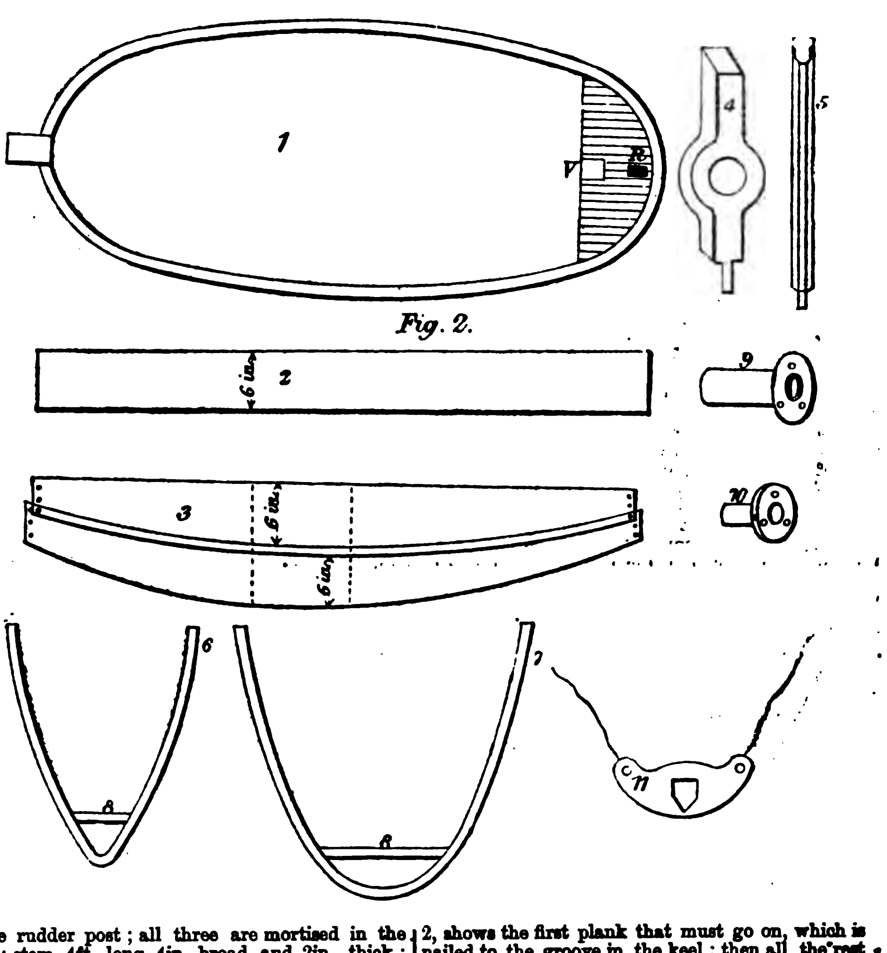


Some use copper nails and washers, but they are dear. Whatever width you bend your middle ribs will be the width of boat: they are spiked to the keel as in Fig. 1; then nail about 4 hardwood laths to the inside of ribs, from stem to stern, at each side of the boat, and at equal distances apart, to strengthen framework, and, as lines to go by, when laying the planks on as shown in Fig 1, *m m m m*. The planks should be ½in. thick, and are held in their place while you nail them to the ribs, with the clamps L in Fig. 1; they are easily made: two bits of hard wood, 10in. long, 2in. broad, and 1in. thick, with a piece of wood put through two slits in them and a pin at each side. Bottom part is clasped on the rib and planed and a wood wedge driven in the top. You will want twelve of them to hold the plank close to the ribs all the length, while nailing them. Treat the next plank the same. A launch this length, and 6ft. broad, and made like this, will be strong and plenty small enough and quite safe. It will not cost such a deal if you make it yourself. I will help you all I can if you make it. Living at a seaport, I see a deal of launches. Do not make it less than shown. It puts me in pain when I see a boat too small, wallowing in the river with several people in, and nearly down to the water's edge. I will freely lend you two patterns for the bush and the gland to be cast from; and if you advertise your address, I will give you the size of a suitable engine next that will not cost much.—Thomas Thompson.

[52783.] — **Phenylendiamine.** —There are three varieties of this base—viz., ortho., meta. and para. The first of them may be obtained by acting on orthonitrobromobenzene with ammonia, which produces orthonitraniline, and on reducing this with tin and hydrochloric acid, orthophenylenediamine is obtained. This base forms a sulphate which is easily soluble in hot water, but only slightly so in cold water; and possibly by converting the amine into a sulphate, advantage may be taken of the above property to effect the separation for which the querist asks.—Wm. John Grey, Elswick Science School.

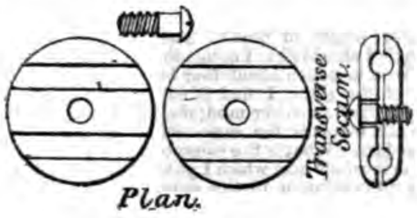
[52785.]—**Hughes Battery.**—1. E.M.F. about 1·0, int. res. 7w. or 8w. Int. res. is dependent on size of cell, thickness of sawdust, and tightness of packing. 2. No use. Use granule or some form of bichromate.—Cosmos.

[52789.]—**Watch Repairing.**—Take the watch all to pieces, take up the balance, and with a sharp knife take off the collet with the pendulum spring attached. Examine the pivots; carefully run it in the calipers to see if the pivots are quite straight. If found to be bent, take a common pliers and bend them gently. These pivots are not very hard, so there is not much fear of breaking them unless very much bent. Then see if the pivots are getting flat on the points; if so, they must be done up again in a pivoting tool nice and round on the points: then put it in the plate-screw, the cock down, and see if it is quite free between the jewel-holes; see that the end stones are sound—if not, put new ones. The cylinder must be quite free upon both ends. Then examine the scapewheel, run it in the calipers and see if it is quite flat; if not, it must be made flat. Put the 'scapewheel in the plate, give it a very little end shake, see that it runs free on both ends, especially on the end next to the bar, as the teeth sometimes strike the inside of the bar, which must be corrected; if so, then place the cylinder in the plate along with 'scapewheel; get the 'scapeteeth to strike the centre of notch in cylinder (not too high or too low), if too low, the back of the 'scapewheel would strike the bottom of cylinder, or if too high the notch of cylinder would strike the flat of 'scapewheel (which we often see by the 'scapewheel recoiling at every beat of watch) which must be avoided. If you put these things correct and the rest of watch be all right, you will have a good going Geneva watch.—Casper Hauser.

[52794.]—**Toning Prints.**—If "Vango" will try the following, I think he will succeed:—Take a 15gr. tube of gold chloride and put 15oz. of water to it. Then to tone the prints, which should be printed until the light parts begin to go slightly brown, take 10oz. of water and dissolve in it 50gr. of borax, then add ½oz. of the gold solution; then proceed to tone the prints, having previously well washed them. The above amount will tone from 16 to 20 prints. After toning, treat with hypo in the usual way. The borax solution must be always mixed when wanted—never before.—C. L. Tweedale.

[52794.]—**Toning Prints.**—"Vango" should wash his prints in three or four different waters. The last washing should leave the water perfectly clear; next put the washed prints into the following solution:—Chloride of gold, 1 grain; acetate of soda, 30 grains; distilled water, 6oz. The prints should be allowed to remain in the toning solution till the red colour has changed to a warm sepia, or darker if required. The prints should be moved about a little to produce equality of tone. Now wash the prints for a minute and immerse in hyposulphite of soda, 2½oz.; water, 10oz., for five minutes. Now wash the prints in running water for several hours; dry and mount.—Photographicus.

[52797.]—**Joining Electric Wires.**—It is quite possible to make thoroughly good joints without soldering, but I doubt if a good level joint could be made without. Doubtless what the engineer had in his mind was a most efficient and beautifully simple joint used by Crompton, as per sketch.—P. Ward.



[52798.]—**Lalande Element.**—A full account of this element may be seen in *Electrical Review*, July 28th, and an analysis of the working in the same journal for Aug. 11th of last year. The elements are caustic potash, cupric oxide, and zinc.—Cosmos.

[52807.]—**Power for Circular Saw.**—"Shadowless Man" cannot hope by any arrangement whatever to get more than about 1¾ h.p. from his piping. Supposing the pipes to be in proper working order, they should be capable of delivering about 57 gallons of water per minute at a height of 125ft. above the outlet, or with a fall of 75ft. in the mile. In other words, if he were to put a tap on the outlet of his pipe, and regulate it so that 57 gallons a minute would flow through, then a pressure gauge on the pipe near the tap should show a remaining pressure of 125ft. This represents a power equal to about 72,000 ft.-lb. per min., or 2¼ h.p. Allowing for losses in the turbine or other motor, he must say 1¾ h.p., and this is the best possible result. In order, however, to get this result, his motor must be so constructed that it will use the 57 gallons per min. fully open to the pressure of the water in the pipe without any throttling or obstruction. If it uses much more or much less, the power will be reduced. If so small a power would be of any use, I believe a suitably-constructed oscillating water engine would be more effective than a turbine. A waterwheel would be of no use unless it were made 125ft. diameter. An efficient air valve should be put on each of the high places of the pipe.—W. Wyatt.

[52811.]—**How to Cause Tar to Dry Quickly.**—Boil the tar for two hours, and when it has again cooled, add, with stirring, benzoline until of proper working consistency. The boiling should be done in the open air, to escape from the unpleasant vapours given off and the risk of fire from the tar boiling over, and in a vessel of sufficient capacity to contain two or three times the quantity of tar operated on.—Gas Manager.

[52812.]—**How to Cause Tar to Dry Quickly.**—I think if you mix turps carefully with your coal-tar you will succeed. Not too much turps, or the tar will be lumpy, and will not mix.—J. B.

[52816.]—**L. and S.W. Engines.**—I regret to say I have not full dimensions of the new bogie-engines on this line (Nos. 445—454). They are somewhat similar in appearance to the 137 class by Beyer, Peacock, and Co. The 445 class have 7ft. coupled wheels, and cylinders 18in. by 24in. (outside).—Meteor.

[52817.]—**S.E.R. Engines.**—Dimensions, and a small sketch of the 81 class appeared a little time ago in the "E. M." The driving wheels (single) are 7ft., and cylinders 16in. by 22in.—Meteor.

[52817.] — **S.E.R. Engines.**—No. 81 class: cylinders 16in. by 22in., driving-wheels 7ft. dia., leading-wheels 4ft. 6in., trailing-wheels 3ft. 9in., and weight about 34 tons. No. 81 was built at Ashford by Mr. Cudworth, and renewed in 1877, by Mr. Watkin. It is fitted with the vacuum brake.—F. W. Brewer.

[52817.]—**S.E.Ry.**—The 7ft. singles, such as 81, &c., were built, some by the company at Ashford, others by the Vulcan Engine Co. of Warrington, about 15 to 20 years ago. Cylinders 16 by 22, grate area (Cudworth's firebox) about 21 square feet, heating of firebox 132¼ sq. ft., of tubes 973 sq. ft. Diameter of leaders 4ft. 6in., of drivers 7ft., trailers 3ft. 9in. Weight on leaders 10 tons 6cwt., on drivers 12 tons 9cwt., on trailers 9 tons. Total weight, 31 tons 15cwt. The engines have double frames, and a wheel base of 17ft. 3in., and are, therefore, rather bad to get round curves. Many have now been rebuilt.—W. B. P.

[52820.]—**Lickey Incline.**—The best account of the American engines used at one time for working this incline is to be found in Dempsey's "Locomotive Engines," Weale's series. The bank is 2¼ miles long, quite straight, and rises 1 in 37 from Bromsgrove to Blackwell.—W. B. P.

[52820.]—**Lickey Incline.**—I scarcely think the querist is correct in saying an American engine draws the trains up this incline, because the Bromsgrove Railway Works are held by the Midland Railway Co., and in addition to the works are three engine sheds, appropriated to the locomotives working the incline, which has a gradient of 1 in 37 (or 37½); it is 2¼ miles in length, and the trains ascend at the rate of 8 to 9 miles an hour.—A Member of the Society of Engineers.

[52820.]—**Lickey Incline.**—The gradient of this line is 1 in 37. I have not the length by me at present, but will send soon. There were 12 American engines built for this line by Norris, of Philadelphia, 1840: Outside cylinders, 10½ by 18; single pair of driving wheels, 4ft. dia.; 4-wheeled truck, wheels 2ft. 6in. dia.; 78 copper tubes, 2in. dia., 8ft. long, weight 9tons 11cwt. 1qr. With the Editor's permission I will send a sketch of one of these American engines, as I believe it will be interesting, also a few of their performances. I would send them now, but have not got them by me at the present moment. The Lickey incline was afterwards worked by 6-coupled goods engines (M.R. 350 class, Kitson, 1855), and in 1861 four well-tank engines (double frames); Nos. 220—223 were built specially for this traffic. These had 6-coupled wheels, 4ft. dia., and cylinders 16½ by 24. The Lickey is now worked by Johnson's side tanks, 6-coupled 4ft. 6in. wheels; cylinders 18 by 24. Meteor.

[52821.]—**N.E.R. Engines.**—The following are the dimensions of the new bogie engines building at Gateshead: Cylinders, 17 by 24; bogie wheels, 3ft.; coupled wheels, 6ft. 7in.; wheel base, bogie, 5ft. 3in.; wheel base bogie pin to driving wheel, 9ft. 7in.; wheel base coupled wheels, 8ft. 4in.; boiler dia., 4ft. 1in.; length 10ft. 2¾in.; 190 tubes, 1¾in. dia.; length of firebox, 5ft. 6in.; heating-surface, firebox, 100 sq. ft.; tubes, 913·8 sq. ft.; total, 1013·8. The engines are to be built from Mr. McDonnell's designs, for the express trains between York and Edinburgh.—Meteor.

[52827.]—**Ramsbottom's Scoop for Locomotives.**—"Feed-Pump" is quite correct in his interpretation of the formula. But he must remember that, with a pipe of uniform dia., the column of 52·25ft. will just balance the effort of the water to ascend, and there will be no flow or discharge. If he cuts one foot off the top of his pipe, he will have an 8ft. per second flow; if two feet be cut off, an 11·3137ft. per second flow, and so on. Further, he must allow for loss through bend in his pipe; say, for a quarter bend, he would have an 8ft. per second discharge at 51·25 / 1·5708ft. and an 11·3137ft. per second discharge at 50·25 / 1·5708ft. A small further allowance should be made for viscosity (commonly called "friction").—G. Pinnington.

[52829.]—**Manchester and London Expresses.**—Although I take great interest in all relating to matters like the above, yet I fear my views on the query would not be of much service, and I always try to keep in remembrance the extract from Montaigne at the beginning of the Correspondence columns.—Wm. John Grey, Elswick Science School.

[52830.]—**Coal-Burning Locomotives on M. Ry.**—The two goods engines built by Beyer, Peacock, and Co., in 1858, for coal-burning, had Cudworth's sloping firebox, which is still in use in many engines on the S.E.R. The box is generally 7ft. 9in. long, and is divided by a longitudinal mid-feather, the two valves being fired alternately to prevent smoke. The trailing wheels are got in under the back part of the box, owing to the slope. The engines in question were 16in. 5ft. double-framed goods, were numbered 428 and 429, and were tried for a year against two other goods engines of the same class, Nos. 426 and 427, built at Derby. These had plain boxes, without brick arch or deflector. The Cudworths burnt somewhat less coal, and that of a poorer kind, but the saving did not pay for the cost of the system. Nos. 426 and 427 were then fitted with a brick arch or deflector, and another year's trial was made, resulting in a great victory for the latter plan. 428 burst at Nottingham; she and 429 were rebuilt with ordinary fireboxes, and were running in 1877, and may be still.—W. B. P.

[52835.]—**Cometary Orbits.**—The method of calculating these is very fully explained in a "Treatise on Comets," by David Milne, published in 1828. I fear it is almost impossible to give a useful abstract within reasonable limits; but if the querist cannot obtain the book, might try to do so. The calculation is long and awkward in the extreme, but highly interesting, the work of finding one of the elements being especially so.—Wm. John Grey, Elswick Science School.

[52840.]—**Core Box for Globe Valves.**—Before occupying the inquiry columns with several sketches and descriptive matter, I should like to be certain as to the exact kind of valve meant. Is it, as I presume, one of a type common as regards internal shape, alike to steam, escape, and check-valves, in which the fluid coming along the entering tube passes up (or down) a pierced diaphragm, occupied with a lift valve in the centre of the globe, and onward through the exit branch—the face of the diaphragm and its valve lying parallel with the longitudinal axis of the cock, and in the same plane as the hand wheel, if a steam valve? My MECHANICS begin with Vol. XXXI., so I cannot refer to the article you mention. If, however, this is the kind of valve meant, it is not an easy job, except for a patternmaker. Please let me know whether my supposition is correct, and I will contrive to make the matter clear. I have such a valve roughly outlined among "Papers on Pattern Making," and will, if the right thing, give it you in these columns.—J. H.

[52843.]—**Dynamo Making.**—I do not advise you to make such a small machine as you propose, on account of the high speed you are obliged to drive them (3,000 per minute), and also the heat generated if kept running for more than a quarter of an hour. If you have power to drive it, I should recommend you to make one with an armature from 4in. to 6in. diameter. It is impossible to give you an answer to your query as to size of wire, as you do not say if you want it for lighting or plating. Weight for weight, you would have more power in the wrought iron (F. M.'s); but I don't think it would compensate you for the extra expense that wrought iron would incur over cast iron. You had better make a full-sized sketch of the proposed machine, with the legs 8in. long by ½in. thick and see how it looks. About 12 B.W.G., double cotton-covered, will do for the F.M.'s, and about five layers of it; size on armature will depend on what you want it for.—VOLT.

[52846.]—**London Univ. 1st B.A.**—

$$\text{Let } \sin.^{-1}\frac{5}{x} = \text{A}.$$

$$\sin.^{-1}\frac{12}{x} = \text{B}.$$

Then, since their sum $= \frac{\pi}{2}$ they are complementary angles.

$$\therefore\ \sin.\,\text{A} = \cos.\,\text{B} = \frac{5}{x},$$

$$\sin.\,\text{B} = \cos.\,\text{A} = \frac{12}{x},$$

$$\text{and } \sin.\,(\text{A}+\text{B}) = \frac{5}{x} \times \frac{5}{x} + \frac{12}{x} \times \frac{12}{x} = 1$$

$$\text{whence, } \frac{25}{x^2} + \frac{144}{x^4} = 1,$$

$$\text{and } x = 13.$$

If the sines be calculated with this value of x, the angles will be found to be 22° 37′ 11·5″ and 69° 22′ 48·5″, their sum being 90°.—H. T. V.

[52846.]—**Lond. Univ. 1st B.A.**—Many questions in inverse notation are best solved by changing into ordinary notation, thus:—

$$\text{Assume } \sin.^{-1}\frac{5}{x} = a,\ \sin.^{-1}\frac{12}{x} = b,$$

$$\text{Then } a + b = \frac{\pi}{2},\ \therefore \sin.\,a = \cos.\,b;$$

$$\text{Also } \frac{5}{x} = \sin.\,a\ \frac{12}{x} = \sin.\,b;$$

$$\therefore \frac{5}{x} = \cos.\,b$$

$$\frac{12}{x} \div \frac{5}{x} = \frac{\sin.\,b}{\cos.\,b} = \tan.\,b;$$

$$\text{That is, } \tfrac{12}{5} = \tan.\,b\ \ \therefore \sin.\,b = \tfrac{12}{13};$$

$$\text{But } \frac{12}{x} \sin.\,b.\ \ \therefore \frac{13}{x} = \tfrac{12}{13}.$$

$$\therefore x = 13.$$

—JOHN F. WILKINSON, A.R.S.M.

[52847.]—**Co-ordinate Geometry.**—Let A x + B y + C = o; cut the axis of x and y in K and L, and let P be f, g, and PN the ⊥ on the line LK. Then:—

$$\triangle\text{PLK} = \triangle\text{POK} + \triangle\text{PLO} - \triangle\text{LOK}$$

$$\therefore \text{PN}\,.\,\text{LK} = \text{OK}\,g, \sin.\,w + \text{OL}\,f, \sin w - \text{OK.OL}\ \sin.\,w\ (1)$$

$$\text{Now OK} = -\frac{\text{C}}{\text{A}},\ \ \text{OL} = -\frac{\text{C}}{\text{B}}$$

$$\text{Also LK}^2 = \text{OK}^2 + \text{OL}^2 - 2\text{OK}\,.\,\text{OL}\cos.\,w$$

$$= \frac{\text{C}^2}{\text{A}^2\,.\,\text{B}^2}(\text{A}^2 + \text{B}^2 - 2\text{AB}\cos.\,w)$$

$$\text{From (1) PN} = \frac{\text{B}g + \text{A}f + \text{C}}{\sqrt{\text{A}^2 + \text{B}^2 - 2\text{AB}\cos.\,w}}\sin.\,w$$

$$= \frac{-8 + 12 - 7}{\sqrt{16 + 4 - 8}}.\ \sqrt{\frac{3}{2}} = -\tfrac{3}{4}$$

—H. H. HARRISS.

[52849.]—**Gas Consumption.**—If "An Old Subscriber" has old and leaky pipes and fittings, his meter will certainly register less if turned off when not in use. He can very easily have his fittings tested by sending to the gas works from whence he is supplied, asking to have his fittings tested. This can be done in five minutes by a force-pump. If faulty, it is worth the trouble to find the leaky place and repair it, as any leakage goes on constantly whilst the meter is turned on, whether the lights are used or not.—T. F.

[52853.]—**Engine Power.**—I am afraid I shall not be able to show "Sammy" in plain figures how to obtain the hyp. log. of his engine—or, more plainly, the number of expansions in the cylinder from the point of cut-off. If "Sammy" will get one of the Irish "Arithmetics" in use in the Irish National Schools, he will find a table of numbers brought into common log., and then multiply by 2·3026 to change into a hyp. log., he will be able to make his own. So if you divide the length of stroke by the distance the piston has travelled when the steam is cut off, you will get the number of expansions, or 45in. ÷ by 26in. = 1·73 expansions; and by looking at the table that I gave to "Anxious One," you will find that the nearest hyp. log. to 1·73 expansions is ·560 plus 1; so I should work with that log. to find the average pressure. I think the inspector informed you wrong when he told you that the boiler pressure was same as engine; as there must be a greater pressure in boiler to get an average pressure of 27lb. in cylinder with the cut-off as given. Of course, I am reckoning from pure vacuum line; so if you look at the steam gauge, and add 15lb. for atmosphere, and multiply the terminal pressure in cylinder by the hyp. log. ·560 plus 1, and deduct the back pressure in condenser, you will get the average pressure in cylinders, and proceed by the information given in back numbers to find the horse-power.—FIRER, Dewsbury.

[52859.]—**Electricity and Steam.**—The effects are due to static electricity generated by the friction of the passing steam. For a full account of this phenomenon, and a description of the Polytechnic Inst. engine constructed, for investigation into it, see Bakewell's "Electric Science," page 92; edition of 1853.—COSMOS.

[52862.]—**Chemical Problems.**—The 851·4 volumes of air at 537·4mm., and 4° centigrade must be corrected to standard conditions for which we have—

$$v = \frac{851{\cdot}4 \times 537{\cdot}4 \times 273}{760 \times 277} = \frac{124909064{\cdot}28}{210520} = 593{\cdot}3.$$

The volume which disappeared on explosion is 657·06 − 374·73 = 282·33, one-third of which, or 94·11 is oxygen. Hence we have—

$$593{\cdot}3 : 94{\cdot}11 :: 100 : x$$

and—

$$x = \frac{9411}{593{\cdot}3} = 15{\cdot}86 \text{ per cent.} \therefore \text{N} = 84{\cdot}14 \text{ per cent.}$$

It seems to be rather curious air. The second question is apparently from Lupton's book, the data being divided by 2. Taking strontium to be a diad, and denoting its atomic weight by x, the molecular weight of the crystallised chloride is evidently 179 + x; and the molecular weight of the sulphate is 96 + x. We therefore have—

$$\begin{aligned} 179 + x : 96 + x &:: 5 : 3{\cdot}442 \\ 616{\cdot}118 + 3{\cdot}442x &= 480 + 5x \\ 136{\cdot}118 &= 1{\cdot}588x \\ 87{\cdot}36 &= x. \end{aligned}$$

Of course the accuracy of this result depends entirely on our correctness as to the formula of the chloride and sulphate, and if strontium is taken as monad or triad, we will get a different number for x. The best criterion of the atomic weight is that derived from Dulong's law respecting specific heat, with which, doubtless, the querist is familiar. I cannot, however, find that there has been any determination made of the specific heat of Sr, so we must fall back on somewhat indirect evidence. The sp. ht. of calcium is ·167, and therefore its atomic weight is 40, and it is a diad, and looking to the strict analogy between Ca, Sr, and Ba, which metals form an exceedingly well-marked group, we are led to conclude that Sr is diadic. Again, the sp. ht. of $SrCl_2$ is ·1199, and this also favours the view of the molecule containing three atoms. It is, of course, impossible fully to discuss all the facts bearing on the atomic weight assigned to a metal, within the limits of a reply to query; and I have merely given an outline. The querist will find it most interesting and instructive to study the points of analogy in the alkaline earth's group. The next question is merely one of arithmetic. The ash left by a piece of filter paper 60 centimetres square is ·1062 gram. Therefore, one square centimetre will leave

$$\frac{{\cdot}1062}{3600} \text{ grm.}$$

The filter paper of 5cm. radius will have an area of 78·54 square centimetres (the area of a circle being equal to πr^2). The weight of its ash will therefore be—

$$= \frac{{\cdot}1062 \times 78{\cdot}54}{3600} = {\cdot}00231\text{grm.}$$

The querist can calculate the ash from the other sizes given. This question is No. 19 in Thorpe's book. In the last question, which is No. 161 in the aforesaid book, let x denote the atomic weight of carbon; then, for acetate of silver, we have—

$$143 + 2x : 108 :: 28{\cdot}803 : 18{\cdot}612.$$

$$\begin{aligned} 2661{\cdot}516 + 37{\cdot}224x &= 3110{\cdot}724 \\ 37{\cdot}224x &= 449{\cdot}208 \\ x &= 12{\cdot}067. \end{aligned}$$

For tartrate of silver, we have—

$$316 + 4x : 216 :: 16{\cdot}22 : 9{\cdot}6175.$$

$$\begin{aligned} 3\qquad 3039{\cdot}13 + 38{\cdot}47x &= 3503{\cdot}52 \\ 38{\cdot}47x &= 464{\cdot}39 \\ x &= 12{\cdot}071. \end{aligned}$$

For malate of silver, we have—

$$300 + 4x : 216 :: 25{\cdot}898 : 16{\cdot}059.$$

$$\begin{aligned} 4817{\cdot}7 + 64{\cdot}236x &= 5594{\cdot}148 \\ 64{\cdot}236x &= 776{\cdot}448 \\ x &= 12{\cdot}087. \end{aligned}$$

My answers do not exactly agree with those in Thorpe, because I have used the nearest integer for the atomic weight of silver, and Thorpe gives 107·93 as the more correct value.—WM. JOHN GREY, Elswick Science Schools.

[52865.]—**Barrel Organ.**—I should advise the querist to have two 4-octave sets of reeds of F scale, one of 8ft. pitch, and the other set 4ft. The best plan perhaps to adopt would be to purchase an ordinary 2-row tubeboard and reeds, and cut off the lower octave of each row. He can have the whole five octaves, if that would not be too much; but I suppose that would eventually be too clumsy for him. However, he must use his own judgment in this case. As regards the bellows, it makes no difference whether it is placed vertical or horizontal, except for consideration of space. The power or pressure of wind depends greatly on the power of the spring which is placed inside reservoir.—G. FRYER.

[52867.]—**Feed Pump.**—There are various ways of finding the amount of water your pump will force into the boiler. The simplest rule that I know, in my opinion, is to square the diameter of pump barrel in inches, multiply by ·034, and by the length of stroke in feet, and by the number of strokes per minute, or thus:—

$$\begin{array}{rl} 2{\cdot}25 & \text{dia. of pump} \\ 2{\cdot}25 & \\ \hline 1125 & \\ 450 & \\ 450 & \\ \hline 5{\cdot}0625 & \\ {\cdot}034 & \\ \hline 202500 & \\ 151875 & \\ \hline {\cdot}1721250 & \\ 3 & \text{ft. stroke} \\ \hline {\cdot}5163750 & \\ 45 & \\ \hline 25818750 & \\ 20655000 & \\ \hline 23{\cdot}2368750 & \text{gal. per min.} \end{array}$$

Call it 23¼ gallons, providing the pump was full every stroke.—FIRER, Dewsbury.

[52870.]—**Zinc Organ Pipes.**—These pipes are generally tuned by the cones; but some of the metal organ pipes are tuned by a small piece of sliding metal situated at the top of the pipe. In the latter case the pitch is sharpened by raising the metal, and flattened by slightly pressing it downwards over top of pipe. In using the cones for the zinc pipes, to sharpen the pitch, it is necessary to insert the solid cone in the pipe at the top, and by a slight pressure on the cone the pipe is sharpened. To flatten, the hollow cone is placed over the top of the pipe, and being slightly pressed, brings a small portion of the metal over the top of the pipe, which has the desired effect. Great care is required in tuning the organ, and some degree of skill is required in using the cones. Not having made any organ pipes, either metal or wood, I am unable to furnish any further information which is required by the querist; but I know that some valuable information will be found on the subject in some of the early volumes of our "E. M." I take this opportunity of asking some of our organ-building correspondents to furnish instructions how to make paper pipes. When properly made, they produce an excellent quality of tone, and as this information has never once appeared in the "E. M.," I should be exceedingly obliged if someone who is able will kindly send the information for the benefit of some of our musical readers.—G. FRYER.

UNANSWERED QUERIES.

◆

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

Since our last "Volt" has replied to 52473.

QUERIES.

◆

[[illegible].]—**Cough Cure.**—I got from the replies to queries in the "E. M." some time ago a cure for whooping-cough, which I gave to my two children with an effect so magical, that I am exceedingly grateful to the gentleman who sent it. I refer to the bromide of ammonium cure. They never had a severe fit after the administration of the first dose. And now will some kind reader of this, our highly-prized old friend, the "E.M.," please give a recipe for an ordinary cough—one that can be relied on? I keep a shop in a densely-populated place, and many a time my heart is pained to hear the poor people cough—that hard hollow cough which grates so on one's feelings. I want it to give away to those who are too poor to purchase, and to those who are able at cost price; so that the misery of a disease consequent on living in a cough-producing climate may be in some degree alleviated?—David, Belfast.

[[illegible].]—**Governors.**—To "Engineer," and Others.—I see some traction engines having large balls, say 4½in. diam., while others have balls only 2½in. diam. Please say what advantage have the large ones over the small ones, or vice versa?—Engine Driver.

[[illegible].]—**To "F.R.A.S."**—In a work published in 1882, entitled "The Heavenly Bodies," it is stated that Neptune possesses two moons, the second of which has been discovered within the last few months by Lassell. Apart from the fact that Mr. Lassell died in 1880, what authority is there for this statement? The work in question also contains some palpable errors which shake one's faith in its general reliability—e.g., Saturn is stated to have seven moons, Uranus six, and the axis of Mercury is said to be "7 degrees inclined to the plane of the equator, so that there must be a great inequality in the days and seasons"! If "F.R.A.S." has read this book, I should be glad to hear what he thinks of it, as it strikes me that the whole work is written by a man with a preconceived opinion, to which end he weaves in all his statements, without being a master of the subject on which he writes.—E. D.

[[illegible].]—**Battery, Chloride or Granule.**—I shall be obliged if some one will kindly inform me how to obtain a longer duration of power. I use for bells and telegraphs only. If I increase the chloride of zinc, it eats the zinc plates too quickly. If I substitute chloride of ammonium and muriatic acid, the E.M.F. expires in about a month (the ch. of zinc plan lasts three months). How should I increase the quantity of ammoniac or the acid? The cells are excellent for a month, and then expire very rapidly. Would there be any advantage in making the bichromate and acid solution of outer jar two parts acid to one part bichromate solution, now it is in the reverse proportion? I think I ought to say that the zincs are not affected much by the chloride of ammonium, yet plenty of current is generated for some weeks.—R. [illegible].

[[illegible].]—**Jet or Vulcanite?**—I have a quantity of the above that have gone brown. Will some of our friends inform me how to restore them to their original blackness and freshness?—J. B. P.

[[illegible].]—**Analysis of Coal Tar.**—Will some analyst kindly tell me how this is analysed on the small scale in a laboratory? What is usually determined, and how is it done? I know of no book giving that information, and shall be glad to hear if there is one published.—[illegible].

[[illegible].]—**Analysis of Oil Cake.**—Will any practical hand say what is usually estimated in making an analysis of the above, and how the constituents are separated? The title of any book giving that information will also be of value to me.—Augustus.

[[illegible].]—**Gas for Boiler.**—Many thanks for Thos. Fletcher's reply to my query. I see no reason why gas should not burn, the tube being 6in. in diam., because when I put a gas tube at beginning of boiler, the flame ran right along to the end of fire-box. But if solid fuel would be best, would you kindly tell me what form of grate, which, if any, &c., to have? as I have not been able to make a fire burn on the grate I now have.—[illegible].

[[illegible].]—**Leclanché Battery.**—Could some reader kindly tell me the chemical reactions of the Leclanché—the formation, chemical composition, and cause of the different crystals produced by working this cell, the white [illegible], and also long hairy crystals which [illegible] by rapid exhaustion? Also any good treatise, [illegible] on the above battery.—Iolanthe.

[52882.]—**Improving the Voice.**—Dr. Moffat lately delivered in Glasgow a lecture describing the benefits to be derived from the inhaling peroxide of hydrogen as a means of improving the voice. I should be glad if any one could tell me in what proportion the gases are mixed? what quantity should be inhaled at a time? and how long before it affects the voice?—Vox.

[52883.]—**Negative Plates for Battery.**—Will David Gilmore kindly tell me how he reduces gas-retort carbon to powder (which I find very difficult to do), or would soot or lampblack, which is pure carbon, I believe, answer the purpose as well?—W. E. H.

[52884.]—**Engine Query.**—Will any of our readers be kind enough to assist me out of a difficulty I am placed in? I have a 2h.p. engine driven from a boiler that is placed about a dozen yards away from it, and is placed about 6ft. lower. The steam pipe is underground, and passed through earthen pipes. I should be glad if some one will instruct me how to get rid of the condensed water, and prevent it passing through the engine?—Beta.

[52885.]—**Ancient Lights.**—Will some one who knows kindly state how near I may build in front of an "ancient light," and say a word or two on the law generally thereon?—Old Ploughman.

[52886.]—**Dynamo.**—Would "Sigma" kindly assist me in the following difficulty? I have made a small dynamo with a Siemens H armature 1¾in. by 5½in., wound with about 60 yards No. 22 c.-c. wire; field-magnets wound with 78 yards of No. 16 and 42 yards of No. 18 outside of the No. 16,—120 yards in all. I can get no spark from it when driving it at 1,800 revs. per min.; but by exciting the F.M. separately I can heat an incandescent lamp of 50 ohms resistance to redness. Is that a fair test for it, or not? Having made the armature with iron ends, will that have any serious effect on it, or is the resistance of F.M. too great, so as to render the action of armature useless? It works well as a motor.—Ignoramus.

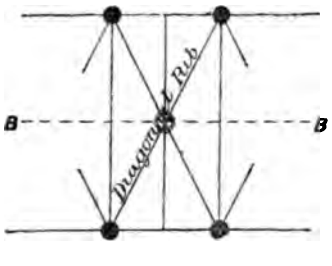
[52887.]—**The Clun Stone Circle.**—Will "F.R.A.S." kindly say if I should not rather look to the Precession of the Equinoxes for a cause of the change in the point of sunrise the gnomon connected with this circle would seem to indicate? In looking over Lyell's "Principles," I find he would divide the great cycle of 21,000 years into four quarters, and to the third quarter would give "long Arctic nights between lat 70° and the Pole, and short days with the sun at a moderate height above the horizon in all temperate latitudes." Then the point is, Would the sun in Neolithic times rise on the shortest day 8° further S. than at present? It seems to me that I have settled the date of this circle.—Neo.

[52888.]—**Induced Current.**—Will any one kindly enlighten me on the following?—On putting a galvanometer in circuit with secondary wire of small telephone induction coil, I find immediately a current is put through primary wire, needle is deflected. Does this show bad insulation of coil wires, or has an induced current magnetic power?—R. F. S.

[52889.]—**Induction Machine.**—Would some one kindly inform me, from personal experience, whether ebonite discs would be as efficient in Wimshurst's influence machine as glass, as I am afraid there would be a difficulty in obtaining the glass; and are these machines as efficient as a Voss with same size discs?—Electro.

[52890.]—**Lunar Queries.**—I am anxious to obtain a lunar cycle in which the moon will return to the same place on the same day, or very nearly so, with regard to the earth, and the same position relative to the sun. This, I believe, is called the Metonic Cycle. Would 1865 agree with 1884? I am aware that these positions would not agree with the distance of the moon or the cycle of her apogee and perigee. If there be any lunar cycle in which the moon returns to the same place with regard to the earth at the same time, with the same position relative to the sun, and also having the same distance from the earth, perhaps some of your correspondents, more learned than I, would tell me. Such a period has, I believe, never been calculated up to the present, if there be such a one in nature. What also is the relative difference of the orbit of the moon when in perigee and apogee? The moon is nearer the earth in perigee. What quantity would represent the difference from the point of her apogee?—George.

[52891.]—**Architectural.**—The sketch is the plan of a Gothic vault of any dimensions over one bay of the nave of a church. Will some one kindly inform me how to obtain the curve of the diagonal ribs in elevation when a section is taken, as shown by the dotted line B B?—Anxious.



[52892.]—**Polishing Paste.**—I should feel obliged if any of your readers could furnish me with a really good recipe for making metal polishing paste. I have seen a German preparation, a red pomatum, which does not harden and crack with keeping, and which produces a very good polish, particularly on brass.—Silver-Bright.

[52893.]—**Lantern Lenses.**—Having purchased a second-hand biunial lantern, I find that the lenses are single (one condenser and one object-glass) to each lantern. Will Mr. Laucaster or any friend tell me what the difference will be between this and one with double condensers and object-glasses? The cons. are 3¼, object-glass 1¾, and, strange to say, both cons. and object glass are achromatic.—Brum.

[52894.]—**Dynamo.**—To Mr. Bottone.—I thank you for the interest I now take in this, and anxiously look for your admirable articles. In an advertisement it is said to be 20-c.p. This is a technical term I do not understand. Would you oblige by giving the size of a room it would light fairly well?—Asta.

[52895.]—**Legal.**—Early in August last I electroplated a bracelet for a person living near me. When finished, I, knowing that they were not the most prompt in the world at making payments, sent to say it was ready. I have twice spoken to them about taking it away; evidently they are not prepared with the needful. Can I sell it to defray expenses, or what is my remedy?—J. B.

[52896.]—**Zinc Labels.**—What is the best fluid to use to write the names of fruit, rose trees, &c., on zinc labels that they may be legible and not wash off? I find the ordinary acids from acting too powerfully on the metal cause the letters and words to run one into the other.—A. Lloyd.

[52897.]—**Moving Lantern Slides.**—Wanted, instructions how to make such slides as Snowstorms, Choreutoscopes, Kaleidotropes, and others. I have the necessary tools, lathe, and materials.—A. E. H.

[52898.]—**Improved Carrier for Lantern Slides.**—I read with considerable interest the paper on p. 423 (Jany. 18th) of your journal on the Improved Carrier for Lantern Slides. I have a difficulty in understanding how the slide is expelled from the carrier, and shall be glad to have further information. It is a question whether it is desirable to so quickly change a lantern view. I shall be interested to learn what your readers think on the matter.—Arcanum.

[52899.]—**To S. R. Bottone.**—Can I drive a dynamo made according to your instructions so that I can light four Swan's 5-c.p. lamps without damage to the dynamo, and at what number of revolutions per minute would it have to be driven (say) for a continuous light of six hours?—Electric.

[52900.]—**Water, Steam, or Sand Bath.**—Would some reader kindly furnish me with a simple design for a water, steam, or sand bath which might be used with safety for the evaporation of alcohol out of turpentine? All that I want is a small one which will give a steady heat of about 180° Fah. to a pint of material. I would like the vessel containing this to be at least two yards from a Bunsen burner which I have fitted up in a garden.—A. Howland.

[52901.]—**Working Models by Electricity.**—I am making a working model to work for a penny, and the common eight-day clock-spring is rather too weak for the movements. Could any of your readers inform me if it could be worked by electricity, what kind of apparatus to get for it, and what space it would take up?—D. T. W.

[52902.]—**Photography.**—Is there any way of developing a latent image on the ordinary sensitised albumenised paper, as can be done on a gelatino-chloride dry plate?—J. B.

[52903.]—**Atmospheric Pressure.**—As the pressure of the atmosphere tends to raise bodies, would it be correct to say that a person will feel more oppressed on a high mountain than at the sea-level, or do other laws counteract this?—J. B.

[52904.]—**Gas Generator.**—Would some kind reader kindly give description of gas generator suitable for one of Fletcher's 2lb. injector gas-furnaces for casting brass, as I believe there are several beside myself who would prefer to make their own? Am a fair sheet-metal worker. Any information would be acceptable to—Generator.

[52905.]—**Gas Threads.**—Would any reader oblige me by letting me know the number of wheels wanted for cutting gas threads in the lathe from 2in. down to ¼in. pipe? The lathe I have to cut them in is one of Campbell and Hunt's screw-cutting lathe. The travelling screw is ½in. pitch, and have wheels from 120, 110, 100, [illegible] 90, 85, 80, and so on down to 20.—Young Beginner.

[52906.]—**Small Dynamo.**—To Mr. S. R. Bottone.—I wish to construct a small machine on Heinrich's principle capable of maintaining 14 lamps 10-candle power Swans. Will you kindly give me the size of machine, the number of wire for field-magnets, the size of ring, and number of wire for same? I am at a loss to understand how this annular core is constructed! Is it an iron casting, and would it not be better to wind the armature with a gap in the iron core so as to slip the coils on, then fill up with a piece of iron to complete the iron continuity?—A. Wilkinson.

[52907.]—**Circular Saw on Lathe.**—I have found this a nuisance, as I cannot saw a piece of wood in two 18in. long, because the head of the lathe is in the way. How can I adjust a pair of centres so that the edge of the saw will come quite 1in. above, and to be worked by the lathe-head? Others must have found the same difficulty, and stop short the same as—Jobbing John.

[52908.]—**Stained and Coloured Glass.**—[illegible] this is so very fashionable, would not a few lessons in "ours" be acceptable to ornament our back windows to hide the unsightly view of bricks? Should be glad to know the probable cost of the lead and the different glasses before proceeding. And, can a pattern painted in colours be burnt in by one of Fletcher's gas apparatus at home?—Jobbing John.

[52909.]—**Barlow's Wheel.**—Will any of "ours" kindly explain the theory of the action of this piece of electrical apparatus? I should like to know how both forms work—viz., the copper disc wheel and also the stellar wheel. I have the instrument and can make it revolve, but cannot find the action explained in any text-book.—E. D.

[52910.]—**Photographing Gas Flame.**—I should be glad if some of your photographic correspondents would kindly say what is the very simplest plan of getting a photographic picture of a gas-flame? A negative on paper would suit my purpose, as I only require one at a time. I may say that I have experimented with [illegible] paper, but the trouble is rather too great. Is there a simpler plan?—J. Thorp.

[52911.]—**Electric Motor.**—To Mr. S. Bottone.—I am constructing an electric motor similar to the one you are illustrating in the present vol. of "E.M." Size of limb on field-magnets 4in. wide and 5in. high from pole faces; pole faces are 6in. long and made heavy; the armature (Siemens) is 6in. long, and the web ½in. thick and 3in. diameter. What I want to know is this—Will these sizes do? I have got 10lb. of No. 14 c.-c. wire, B.W.G. Will this be enough for the field-magnets? If so, how much wire, and what size, shall I want for the armature? Should the resistance in armature be the same as field-magnets? Should I insulate each layer of wire on field-magnets with calico varnished with shellac? Or, will paraffin wax be sufficient?—Alfonso.

[52912.]—**The "Edco" Battery.**—To "C. R. H."—I have 26 carbon plates 5in. by 2in. by ⅜ thick. Will these do for a battery after the principle of the "Edco" battery or the automatic battery as advertised in "E.M."? If so, will you kindly give me particulars for the construction of one?—Alfonso.

[52913.]—**Armature.**—To Mr. Bottone.—I have an armature made up ready for winding in malleable iron, and I have been told it is not any use because it is too hard—it ought to be special iron. What is special iron, and where can it be obtained? If Mr. S. Bottone will inform me, no doubt he will oblige others besides—Volt.

[52914.]—**Dynamo.**—To Mr. Bottone.—A dynamo at 1,100 revolutions per minute gives off 5 volts and 40 ampères. What would the increase of current be if speed was raised to 1,600? Armature 6in. dia., 5in. wide, and wound with 9lb. of 14 wire, 40lb. of 10 wire, on magnets. Can you give me some instructions how to make an instrument to measure the ampère current of a dynamo?—Volt.

[52915.]—**Violoncello.**—Is this instrument made in the same way as the violin—i.e., with inside or outside mould? How are the ribs bent, and what is the thickness of them? What special tools are required? Does beech wood or maple turn out the best job as regards tone, and can the front be made in one piece if a very equal piece of pine can be procured? Would any reader kindly inform as to the above, or refer me to the back numbers of the "E.M.," where the subject is fully treated? I can find little or nothing on the subject in the last three vols. beyond certain measurements, &c.—A. H. S.

[52916.]—**American Organ.**—Would Mr. Fryer or "Organon" kindly give me size of bellows and reservoir required for an organ I propose to build containing two manuals, the upper one consisting of 3 rows, and the lower one consisting of 3½ rows; also 2 octaves of pedal notes with octave coupler on lower manual? I may add the recess I propose to place it in is 4ft. by 2ft. 6in. Any other information respecting the strength of the springs and the distance the bellows will require to open will greatly oblige—American Organ.

[52917.]—**Gas Flames.**—To Mr. Thomas Fletcher.—Will you kindly answer me the following question?—Many years ago I understood from a gas authority that if a gas flame was turned low when not required the consumption of gas was at least as much as when fully burning. His words to me were—"It consumes more gas without giving a better light." Is this so? We must perhaps take into consideration the improvement in gas burners since thirty years ago.—Geo. H. Lancaster.

[52918.]—**Transmitter.**—To Mr. Strangways.—Having constructed transmitter according to directions given in recent number of "E.M.," should be glad to know the object in making the piece of wood attached to one cone of carbon longer than other; and, also, is lead wire used simply for a weight? Will shot flattened out do as well? Not having seen description of your clear-speaking telephone in "E.M.," should be glad to learn the number; and can one be used in private house without infringing any rights or patent?—Electron.

[52919.]—**Electrotyping.**—Will some reader kindly explain the following? I have a dynamo that gives 42 ampères and 3 volts at 1,100 revs. per min., and when I put my work into circuit the machine will work for a few minutes and then the current dies away. Will some one tell me where I am wrong? Also how many square feet a machine giving out the above power will deposit on, and at what rate? I want to deposit the copper in small pieces about 1⅞in. long, 5-16in. thick, and in various widths from ¼ to 2in. Cathodes are of metal. Is the solution the same for the machine as for the battery? If not, what is the difference? It takes about five weeks to get the above thickness with Smee's battery working constantly. How long will it take with the dynamo? Can Mr. Bottone give me any information?—Volt.

[52920.]—**Legal.**—A. died on the 1st June, 1881, leaving to her niece, B., all her personal estate, consisting of gas, railway, bank, and other shares. Owing to technical legal difficulties the estate of A. had to be thrown into Chancery. On the 17th December, 1881, B. died also, making no will, and the Chancery suit undecided. We expect the Chancery suit to be tried out soon, and the question is, To whom does the money belong? The husband of B. claims the money, and says what belonged to his wife belongs to him. The children of B. think they are entitled to the money, and they wish to prevent their father having the money, because they know that he will leave it all to their step-mother. Will some of your legal correspondents kindly enlighten us in this matter? Does the estate of B., under the circumstances named, belong to the husband of B., or to the children of B.? The estate of A. does not include any real property.—S. Barnett.

[52921.]—**The Action of the Pump.**—To Mr. P. J. Davies.—Can it in practice make any difference in the effective working of a pump that the greatest rise in suction pipe should occur at a point about two-thirds the distance between the well and pump—the pipe having a fall both ways, highest point being 22ft. above well and 6ft. above pump? Plumber (who has spent two days trying without effect to make it draw) says the cause of his failure is this rise and fall in the suction-pipe; and that in a similar case he once had before the difficulty was got over by raising the pump till a continuous fall to the well was obtained, and then that pump drew the water without any trouble. It seems to me that this theory cannot have a foot to stand on.—F. C.

[52922.]—**Legal.**—An association, say, with a working committee of 12, runs into debt to the amount of £15. There appears to be no means of collecting this sum. The committee then resolve to obtain from each member a guarantee for the sum of 25s. each. Eight of these pay their amount; but the other four do not. Can creditors call upon the whole 12 for arrears, or are the remaining four only liable? I may add that in exchange for the above guarantee each member obtains from the association a guarantee that they will not be held liable for anything more than the amount (25s.) guaranteed by them. It is the legality of the latter that I wish to test.—Schiox.

[52923.]—**Micro.-Photography.**—How can I take small pictures, say the size of a pin's head, to be afterwards magnified under a microscope? How can they be developed? Any information will be welcome; but I should like the whole process.—P. C. W.

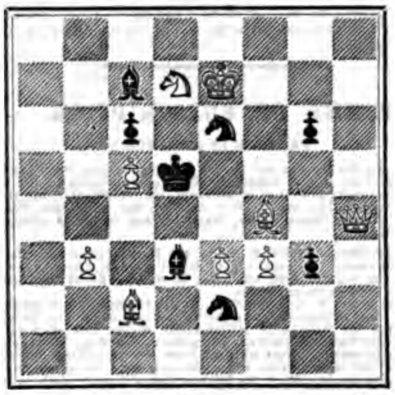
[52924.]—**Removing Tricycle Wheels.**—Can any one possessing a Bayliss and Thomas Tandem tricycle say if nut on outside end of axle (under the gun-metal cap) is intended to be fixed? Want to take wheel off, but cannot move nut with ordinary wrench.—Fixed.

CHESS.

All Communications for this department must be addressed to J. Pierce, Bryn Rhedyn, Llandwrog, Carnarvon.

PROBLEM DCCCLXXII.—By J. B., of Boxford

Black.



White. [9+8

White to play and mate in three moves.

Solution to 870.

White.	*Black.*
1. Q-K Kt 2	1. Anything
2. Anything	2. Q, B or Kt mates

(7 variations.)

NOTICES TO CORRESPONDENTS.

Correct Solutions to 871 by Arcanum (a pretty and difficult problem) and R. A. Bennett (very neat); to 870 by D. Millar, J. G. E. (Sittingbourne), A. Schmucke, Rev. W. Anderson, R. A. Bennett, W. H. Evans, W. J. Francis, and Demetrius; to 869 (second solution) by W. J. Francis, R. A. Bennett, J. G. E.

R. A. B.—It appears to be a true bill.

W. J. Francis.—Your solution of first tourney problem is correct; but it has been sent too late to score.

W. Anderson.—The two works are quite distinct. "Chess Problems," with supplement, are original. "English Chess Problems" constitute a selection of the best problems by English composers. The price of the latter is 9s.

J. Grey.—The games given belong to a Tourney now nearly concluded; but we are about to start a new one, and shall be happy to enter your name. The fee is 5s., to make up a prize fund. Five members have already joined; but a dozen are wanted.

Every Workman connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 31, Tavistock-street, Covent-garden, London, W.C.

"THE BUILDING NEWS" is the Principal Journal, representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

Holloway's Pills are admirably adapted for strengthening debilitated and nervous constitutions. Weak digestive organs are invigorated and poor blood enriched by this purifying medicine. The most delicate may take it without apprehension, the most timid need have no fear. The balsamic nature of Holloway's Pills guarantees their strengthening powers.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

BACK NUMBERS.

We receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Batteries: Nos. 715, 718, 734, 741.
Bellows camera: Nos. 894, 897.
Bookbinding: Nos. 613, 770.
Coils, induction: Nos. 832, 885
Coils, medical: Nos. 844, 898.
Copying processes: Nos. 750, 753, 761, 762.
Electric machines: Nos. 628, 759, 840, 846.
Electro-magnets: Nos. 756, 772, 783, 864, 872.
Electro-plating: No. 833.
Lacquers: Nos. 622, 866.
Magneto-electric machine: Nos. 783, 826.
Silver-plating: Nos. 830, 868, 870, 874.
Telephones: Nos. 692, 695, 747, 781, 809, 828, 846, 853, 865, 894.
Varnishes: 478, 619, 675, 691, 723, 775.

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 30, and unacknowledged elsewhere:—

W. T. Underwood.—W. Robbins.—H. C.—Sydney.—W. B.—Engineman.—Eccleston.—Ferro.—Fluid.—Markham.—Granville H. Sharpe.—Ariba.—J. W.—T. Tindall.—A Jerry Shed.—Cynoru.—G. B.—W. Jones.—M. D.—S. Freestone.—D. and W.—Naphtha.—G. Russell Pridham.—A. W. Lambert.—Mechanic.—P. Ward.—John Hale.—S. G. Hart.—Leigh S. Powell.—Locomotive.—J. E. Gore.—G. J. H.—Ninip.—Apprentice.—L. C.—G. Gray.—C. B.—J. R. Holt. (Merely because the hair is expensive. We think it quite possible that some amateurs could make them as well as professionals, if not better.)—W. F. Holmes. (Two: London and York. The Mayor of Dublin also takes the title. 2. It is partly due to refraction, and partly to the fact that comparison with other objects enables a better estimate of the size to be made. 3. Air currents rushing into areas of low pressure from parts where the barometer stands high.)—P. C. W. (You explain now. We do not think the details have ever been published. There was a descriptive article in Vol. XIV., but the number is out of print. Will insert a query. Two numbers containing tolerably complete instructions in soldering have been forwarded. As to the glue, any good glue; but binders for cheap work use the lowest priced.)—Young Wife. (A dozen queries at once is more than we can manage, especially when most of them have been answered many times.)—Would-be Traveller. (One of Cook's "Tourist Guides" would answer the query fully. Write for particulars to Ludgate Circus.)—Small Power. (For explanation of principle of gas-engines, see p. 101, Vol. XXXIII., and the indices for many references to illustrations.)—Vikil Charon. (What about the temperature? The deepest mine is a mere indentation compared with the diameter of the earth, and it is uncomfortably warm at that depth.)—H. B. B. (Both queries are advertisements. The glasses can be obtained at any large musical instrument warehouse. As to the book, we know of nothing of the kind.)—Lloyd Waymouth. (No one can say without examining it. Read the subject in the articles, and then endeavour to discover the reason.)—Shopkeeper. (See pp. 356, 380, Vol. XXXII., and the indices generally. The question has often cropped up. It is a simple matter of efficient ventilation.)—E. Jones. (The spirit level was first described by Thevénot in 1666, and he is considered the inventor.)—J. M. Wood. (It would serve no good purpose to engrave the sketch. We gave drawings on pp. 112, 247, and 260, and to answer a question why anything made like them does not work would necessitate personal inspection.)—G. P. H. (Apparently, it is the remains of a Daniell. Directions for making up have been frequently given. See p. 537, Vol. XXXVI., or almost any textbook.)—J. K. O'C. (It is much better to buy it than to attempt to make it in small quantities; but you will find recipes for various kinds on p. 311, No. 325.)—L. B. B. (There is the "Micrographic Dictionary"; but that, perhaps, is beyond your requirements. We do not know of any cheap work giving all the more common objects; but try the catalogue of Van Voorst, Paternoster-row.)—Clachan. (The delay is often considerable in the U.S. office before the patent is issued.)—Pirate. [illegible]

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, FEBRUARY 8, 1884.

THE STANLEY CLUB SHOW.

THE seventh annual exhibition of bicycles and tricycles held under the patronage of the Stanley Bicycle Club was opened at the Floral Hall, Covent-garden, last Monday. The change of location is advantageous in some respects; but if makers are to derive any benefit from these annual shows, it is at least essential that the public should be able to examine the machines, and compare their relative merits. The present exhibition, however, is so crammed that although there is just walking space on the floor area, it is simply impossible to get round the galleries with any comfort, for if one or two visitors stop to look at a machine there is at once a "block." It is certainly the interest of the manufacturers to insure ample space in which the public can examine their machines; and on the present occasion one well-known firm refused to accept the stand allotted them, and took their machines away to a temporary warehouse.

Visitors will of necessity have noticed that the tricycle is the machine that nowadays comes to the fore. Amongst bicycles there is, so far as the machines themselves are concerned, little improvement and no novelty to record, if we except the doubtful advantage of a device to enable any one to ride a taller wheel than his legs are suited for with the ordinary patterns. This is an arrangement in which the backbone stops at the rear end of the saddle, and is connected with the head by extension pieces which bend down below the rim of the wheel on each side. The saddle is thus brought nearer to the treadles, and it is claimed that the rider can have a wheel 4in. larger than is possible with the ordinary arrangements. The device is patented; but it will scarcely commend itself to riders. The novelty in the bicycle line is the "Tandem" bicycle of Rucker and Co., which is a novelty as far as exhibitions are concerned, though it is known to experts as a machine that does when well ridden travel at a tremendous pace. It is merely two large wheels joined together by a bar connecting their heads. Each rider, in fact, drives the big wheel of a bicycle, and the small wheels are missing; but as both are connected together by a bar, it is obvious that both riders must drive at exactly the same speed, or there will be slip. Apparently the machine has to be held for the foremost rider to mount, and then when he has got the affair into motion the rearmost gets on by the aid of a step. As there are only two wheels, and each one is driven, it is obvious that, provided both are driven with an equal amount of power, very high speed can be attained; but it is also obvious that steering is not easy, and that expert riders are necessary to prevent an awkward tumble. The novelty of the show is the "Oarsman" tricycle, invented by the Rev, J. M. Taylor, of Seer Green Vicarage—one of our old correspondents. In this machine the action is as nearly as possible identical with that of rowing. The feet are placed firmly against two footplates, and the toes control the steering wheel, which is held firmly in position; in fact the steering is nearly perfect. The seat slides on runners placed at an incline, and the hands grasp a horizontal adjustable bar which is connected to cords on either side. These cords pass over pulleys, two of which, by means of a clutch action, give motion to the driving wheels. The body comes down with the seat by the action of gravity until the knees are bent and the horizontal bar is in close proximity to the feet. The muscles of the legs, back, shoulders, and arms are then brought into play, and the body being straightened, the seat runs up the inclined guides, and a very powerful stroke is given, so powerful that a heavy man like Mr. Taylor can make eight miles an hour on fairly good roads with fifteen strokes per minute. There is practically no exertion in getting forward to the work, so the power exerted is all utilised in driving, save that required to overcome friction of the parts. As a machine for exercise, the "Oarsman" undoubtedly takes the first place; but we suspect that Fashion will prevent its frequent appearance on public roads. Another novelty is the Otto tricycle, with front steering wheel, and centre gear on a swinging frame. We mentioned this machine on p. 312, and now that we have seen it as actually built, can safely say that it is one of the attractions of the exhibition. The arrangement of the steering gear, which practically compels the rider to lean over to the proper side, is a useful feature, and the wheels, with spokes secured to three rims on the hub, give an appearance of immense strength, which has been amply borne out by such tests as have been made. To take the exhibition as a whole, there is not much improvement to record, for although tricycles can be seen in all sorts of shapes, the old and well-known patterns are still exhibited, and still have in some cases the spoon brake, which has been the primary cause of not a few unpleasant accidents. The spoon brake is no doubt very powerful and efficient when applied with equal force to both wheels; but if through some defect one wheel is not held and the other is, the result is obvious There is a tendency to decrease the size of wheels, to prefer enamel to nickel plating, to use tangent spokes, and an evident desire to provide some simple form of gear by which the speed can be altered whilst running. To describe all those devices is impossible in our space; but as a matter of fact most of them are well known—as well known as the extraordinary statements which some makers still persist in putting in their lists. For instance, it is not uncommon to find it stated that "the centre of gravity of this machine is very low," when it is obvious that it is very high. Amongst the machines which especially attracted our attention was the Duplex Tandem Excelsior of Bayliss, Thomas, and Co., Coventry, which is received with much favour by those who require a "sociable." The firm also has a good exhibit of their well-known makes. The Centaur Cycle Co., of Coventry, also show several convertible and combination tricycles which should be seen by those looking out for sociables. Ellis and Co., of Fleet-street, exhibit several Faciles, including that on which Mr. Adams did his famous ride of 242½ miles in 24 hours. Devey and Co., of Wolverhampton are noticeable for an exhibit of serviceable-looking machines at low prices—one being a 52in. bicycle for less than £5. Starley and Sutton exhibit amongst their machines the Rover, a rear steerer, in which the rider sits between the axle and the hind wheel, and directly over the treadles. Some of the objections to rear steerers are overcome in this machine. Mr. Bown, of Birmingham, is as usual present with his well-known bearings, fittings, and stampings, and also a patent speed gear for tricycles. Burdess and Co., of Coventry, exhibit several of their favourite Sterling tricycles, and the South London Machinists' Company, of Tower Chambers, Moorgate-street, show most of their well-known patterns. Their Flying Scud Convertible Sociable is worth the attention of those on the lookout for machines of the class, while the Paragon, a Humber-pattern tricycle, will suit those who want high speed with a wear-and-tear machine. The Antelope is a machine in which the rider sits behind the axle; but it is open-fronted, and can be readily mounted from front or back. The tube covering the axle serves as footrest when running down hill, and the whole weight can be thrown on the treadles when necessary. The Gnat tricycle, shown by the Metropolitan Machinist Company, has 30in. wheels, and is sure to attract considerable attention. Kelsey and Kelsey, of Birmingham, exhibit their ventilated handles, which we illustrated on p. 8 of the last volume. We also noted one or two machines having handles sheathed with cork. Two or three makers show machines with aluminium fittings; but we suspect that metal is still too costly to meet with much demand in the construction of cycles. The Merlin and the Englefield are representatives of those machines which work by a clutch action, in which the stroke given by the leg can be of any desired shortness. Little improvement seems to have been made in folders or telescope tricycles; but the Sutton reducible, to be seen at Stall 75, is, perhaps, the best arrangement for removing one of the wheels in order to get a tricycle through a doorway. In this machine the axle is cut so as to form a sort of scarph joint, which is secured by a couple of nuts with left and right-hand threads respectively. Several machines for carrying luggage are shown—in one case as much as 150lb., which is carried in a basket in front of a rear-steering machine, the weight being supposed to be balanced by that of the rider. There is a demand for machines of this kind, and we expect to see something better produced before long. Altogether, we may fairly conclude that the art of cycle building has reached a high degree of perfection in 1884, and the "fittest" amongst the many patterns are those that will survive.

THE ACHROMATIC OBJECT GLASS.—

XXX.

By W. BRADBURY.

Brewster's Remarks.

IN Brewster's edition of Ferguson's Lectures, published in 1806, there is an interesting article on the object glass; which, though it was written when optical science was in its very infancy, contains information which will still attract attention. A number of tables of different forms are given: I have greatly condensed these, because the ten or twelve horizontal lines of numbers containing the radii for a progressive increase of focus, are but multiples of a standard ratio. This I have taken to be the radii required to produce a focal length = 1·000, as in previous examples; therefore the values of the curves are decimal parts of this quantity.

After explaining how achromatism is produced by media of different dispersive powers, the writer thus proceeds:—

"Having thus discovered that light could be refracted without colour, the next object of philosophers was to ascertain the curvature which must be given to lenses in order to produce this effect, and likewise to correct the spherical aberration. This subject has been treated with the greatest ability by several foreign mathematicians; but particularly by Euler, d'Alembert, Clairaut, Boscovich, and Klugel. The writings of these philosophers furnish us with the most complete and accurate information upon this point; and art has in this case received from science all the assistance which she possibly can bestow. It shall be our object at present to reduce the results of their investigations, either into tables, or into such a form as may be easily comprehended by the practical optician, and thus to furnish the artist with a popular view of this interesting subject. For this purpose, the celebrated Euler has given, in his Dioptrica, two formulæ, from which we have calculated the two following tables, containing the radii of curvature for the lenses of a triple object-glass. The first column contains the focal distance of the lenses when combined; and the six following columns contain the radii of their curvature in decimal parts of the focal length."

In the seven succeeding tables, the crown index is 1·526, the flint index 1·604, and the ratio of the differences of the extreme indices in crown and flint glass, 0·6054.

TABLE I.—Radii of a Triplet according to Euler's first formula.

Focal length.	Convex of Crown glass.		Concave of Flint glass.		Convex of Crown glass.		Hemi-aperture.
1·000	·5008	2·666	·5166	·4843	·5218	·4757	·119

TABLE II.—Radii of a Triplet according to Euler's second formula.

1·000	·2836	2·072	2·146	·2955	·5938	2·500	·0706

"The only person in our country who has written upon the theory of achromatic object glasses is the late learned Dr. Robison, of Edinburgh, who, following the steps of Clairaut and Boscovich, has given an interesting dissertation upon this subject. From the formulæ contained in that dissertation, the following table is computed":—

TABLE III.—Radii of a Triple Object-Glass.

Focal length.	Convex lens Crown glass.		Concave lens Flint glass.		Convex lens Crown glass.	
1·000	·757	·3055	·3055	1·059	1·059	·1067

A telescope 30 inches in focal length, constructed according to this table, bore an aperture of 3·2 inches.

"The reader will observe that only three pairs of grinding tools are necessary for constructing a telescope according to the preceding table; but the work may be performed by only two grinding tools, if we employ the radii of curvature which are contained in the following table, computed from the formula of Boscovich:—

TABLE IV.

Focal length.	Radii of the four surfaces of the two lenses of crown glass.	Radii of the two surfaces of the concave flint lens.
1·000	·640	·528

"The radii of curvature employed by the London opticians are pretty nearly represented in the following table, which is calculated from Dr. Robison's measurements.

TABLE V.

Focal length.	Convex lens of Crown glass.		Radius of both surfaces of Flint lens.	Convex lens of Crown glass.	
1·000	·628	·749	·579	·628	·749

"Two of Dollond's best achromatic telescopes being examined, were found to have their lenses of the following curvatures, reckoning from the surface next the object:—

$$\text{Crown lens}\begin{cases}28\\40\end{cases}\text{Flint lens}\begin{cases}20\cdot9\\28\cdot\end{cases}\text{Crown lens}\begin{cases}28\cdot4\\28\cdot4\end{cases}$$

Compound focal length 46in.

$$\text{Crown lens}\begin{cases}28\\35\cdot5\end{cases}\text{Flint lens}\begin{cases}21\cdot\ 1\\25\cdot75\end{cases}\text{Crown lens}\begin{cases}28\\28\end{cases}$$

Compound focal length, 46·3in.

Both these telescopes magnified from 100 to 200 times, according to the powers applied. The Duc de Chaulnes having in his possession one of Dollond's best telescopes, whose focal length was 3ft. 5in. 4·25 lines, made a variety of accurate experiments to determine the curvature, thickness, and distance of its lenses, and found them to be of the following dimensions:—Radius of first surface next the object 25in. 11·5 lines; radius of second surface, 32in., 8 lines; radius of third surface, 17in., 10 lines; radius of fourth surface, 24¼in.; radius of fifth surface, 24¼in.; radius of sixth surface, 26in., 10·6 lines. Thickness of first lens at its axis, 2·11 lines; thickness of second, 1·59 lines; thickness of third, 2·18 lines; thickness of the whole lens 5·91 lines."

The next extract is very interesting, from the fact that the objective closely resembles one of those described by "Prismatique" It proves that, even in those early times of optical art, this form had been found to give a very satisfactory glass.

"A very excellent telescope, with a double achromatic object-glass, was constructed by M. Antheaulme in 1763, from the formulæ of Clairaut. The lens of flint glass was placed next the object, and was a meniscus with its convex side outwards. The radius of its concavity was 17·25in. and the radius of its convex side was 90·66in. The interior surface of the lens of crown-glass had a radius of 16in., while its exterior surface, or that next the eye, was 90in. These lenses were separated by a piece of card, and formed a compound object-glass, with a focal length of 84, and an aperture of 3in. and 4 lines. Its eyepiece consisted of two lenses; that next the object was a double convex with 18 lines of focal length and 9 lines of aperture. Its first surface, or that next the object-glass, had a radius of 11·5 lines, and its second surface a radius of 7in. 2 lines. The second eye-glass, which was a meniscus, had 5 lines of focus and 2 lines of aperture. The radius of its convex surface was 2·25 lines, and that of its concave surfaco, which was next the eye, was 8 lines. The distance between the two eye-glasses was 9 lines.

"The following table, calculated from the formulæ of Boscovich, contains the radii of curvature for the lenses of a double achromatic object-glass:—

TABLE VI.

Focal length.	Convex lens of Crown glass.		Concave lens of Flint glass.	
1·000	·3232	·318	·318	1·5625

In the following table, calculated from Dr. Robison's measurements, the reader will find the radii of curvature which are employed by the London artists:—

TABLE VII.

Focal length.	Convex lens of Crown glass.		Concave lens of Flint glass.	
1·000	·2938	·3526	·3443	1·1474

"Although it has been the practice in this country to construct only double and triple achromatic object-glasses, yet they may be composed even of four or five glasses, the convex ones of crown glass, and the concave ones of flint glass, being placed in an alternate order. By augmenting the number of media, indeed, a quantity of light must be lost, and the labour of the artist greatly increased; but M. Jeaurat informs us that he constructed a compound o.g. 5in. and 10 lines in focal length, which bore an aperture of 1¼in., while the best achromatic telescopes of 6in. focus constructed in England had an aperture of only 1¼in. To such, therefore, as wish to construct object-glasses of this description, the following table, containing their radii of curvature, may probably be acceptable.

TABLE VIII.—Quadruple O.G.'s.

Mean refraction of crown to that of flint, as 1,000 to 1,045 dispersive power—as 200 to 353.

Focal length.	Radius of six interior surfaces.	Radius of two exterior surfaces.	Aperture. of o.g.
4	3·08	3·56	1·25
6	4·50	5·33	1·50
8	5·92	7·18	1·83
10	7·33	8·33	2·17
12	8·83	10·58	2·25
24	17·33	21·17	2·58
36	25·83	31·67	2·92
48	28·42	42·25	2·25
60	42·92	52·75	3·58
72	51·50	63·33	3·92
84	60·00	73·83	4·17
96	68·58	84·42	4·50
108	77·08	95·00	4·83
120	85·58	105·50	5·17

Though it is demonstrable that a telescope, constructed according to the preceding tables, and formed of glass whose refractive and dispersive power is similar to that which was employed in the formula upon which these tables are founded, will form an image perfectly distinct and colourless: yet it is so difficult to procure flint glass of the same refractive and dispersive power, that it is almost impossible for a private individual to succeed, even after several trials. The London opticians have always at hand a number of lenses of various curvatures and different powers of refraction and dispersion, and by selecting such as answer best on trial, they are enabled to construct an object-glass in which the spherical and chromatic aberrations are almost wholly corrected. Those, therefore, who are not furnished with a sufficient number of lenses must necessarily meet with frequent disappointments in their attempts to construct achromatic telescopes; and the only way of preventing these disappointments and rendering success more certain, is to have a variety of tables, which being founded on different conditions give different curvatures to the lenses. If the artist should be unsuccessful, either from the nature of the refracting media which he employs, or from giving the lenses a greater or lesser curvature than the table requires, he may with very little trouble sometimes, with altering the radius of a single surface, adapt the lenses to the conditions of some other table, and in all probability obtain a more favourable result. With the view of facilitating these attempts, we have computed the eight preceding tables, and for the same purpose we shall subjoin the following different forms of achromatic object-glasses from Boscovitch and Klugel.

Forms for Triplets. Crown index 1·[illegible]. Flint index 1·604. Ratio of differences of extreme indices ·6054, for second and third forms. Focal length 1·000 in all cases.

1st Crown lens, equi-convex, radius..................	·6412	: focus [illegible]
2nd Flint lens, double concave, radii	·5227 ·5367	: focus [illegible]
3rd Crown lens, equi-convex, radius..................	·6412	: focus [illegible]

1st Crown lens, equi-convex, radius..................	·530	: focus [illegible]
2nd Flint lens, equi-concave, radius	·530	: focus [illegible]
3rd Crown lens, double-convex, radii	1·215 ·3046	: focus [illegible]

1st Crown lens, equi-convex, radius	·616
2nd Flint lens, double concave, radii	·5556 ·3790
3rd Crown lens, equi-convex, radius	·616

In the following forms, crown index = 1·5[illegible] flint index, 1·575; ratio of differences of extreme indices, ·6486.

1st Crown lens, equi-convex, radius	·4748
2nd Flint lens, equi-concave, radius	·4748
3rd Crown lens, double convex, radii	·3514 ·4383

1st Crown lens, double convex, radii	·3721 1·5744
2nd Flint lens, equi-concave, radius	·4748
3rd Crown lens, equi-convex, radius	·4748

1st Crown lens, equi-convex, radius	·7963
2nd Flint lens, equi-concave, radius	·4748
3rd Crown lens, equi-convex, radius	·5023

1st and 3rd lenses of equal foci placed inversely—

Crown lens, radii	·7306 ·5325
Flint lens, equi-concave, radius	·4748
Crown lens, radii	·5325 ·7306

1st and 3rd lenses of equal foci placed directly—

Crown lens, radii	·7048 ·5471
Flint lens, radius	·4748
Crown lens, radii	·7048 ·5471

Forms for double object-glasses—

Crown lens, equi-convex, radius	·3306	focus ·3466
Flint lens, double concave radii	·3301 1·533	.. ·4384

Crown lens, radii......	·2168 ·7092	focus .... ·3123
Thickness	·0079	
Flint lens, radii	·4606 ·5740	focus .... ·4397
Thickness	·0031	
Separation of lens	·0031	
Aperture	·0937	

These two forms are calculated from Klugel's formulæ.

By glancing over this list, and comparing the various forms, the reader may gain some knowledge of the wide difference in arrangement advocated by eminent theorists. Euler employed a lens having a minimum of spheric error: Robison and Boscovich endeavoured to get as many equi-curved surfaces as possible, thus

avoiding a multiplicity of tools; Klugel did the same with the double o.g., by making the first three curves alike; Clairaut places the flint in advance of the crown, and in his combination also there appears to have been an attempt to make the four radii in two pairs—that is, both inner sides alike and opposite, and both outer sides alike convex.

(*To be continued.*)

HOW TO MAKE A CHEAP LATHE.—VIII.

Supplementary.

THE task I undertook to perform is now complete, and I therefore proceed to redeem the promise made in answer to letter 21912—to describe in a supplementary chapter the mode of construction of a common gap bed, and the modifications such a bed would entail in our first design.

There are two ways of making beds: one is to construct the pattern like the casting, leaving certain parts loose, and giving due taper, both to external and internal parts. The other is to box up a pattern, and to core out the internal portions. Of these two methods I am going to describe the latter; because, firstly, I have found details concerning taper and dowelled pieces very puzzling to people (even engineers themselves) not actually trained as pattern makers or moulders; but chiefly because with a cored-out pattern there is less chance of an untrue casting being produced, such a pattern being less liable to become rammed winding, or otherwise out of truth in the sand. If I were going to make a small bed such as this is, for myself, knowing the moulder who would mould it, and that I could check it with straightedge and strips in the sand, I would not bother with cores; but if cast in a strange foundry, perhaps by men unaccustomed to this class of work, I would not run the risk of getting a crooked bed by constructing a pattern of so slight proportions. To such as wish, however, to mould in greensand simply, the view of Fig. 99 is self-explanatory. A pattern made thus (one only of two or three methods) will be made correctly for moulding.

Fig. 100 shows a fairly proportioned bed for our headstocks. It might perhaps be lengthened six inches with advantage, dependent upon the class of work for which it is to be adopted. Also iron standards should be substituted for the wooden ones of our cheap lathe. The saddle of the slide rest will also be modified in form. Let us consider each in turn.

The bed, then, first in order. "Box up" the main body of the pattern, Fig. 101. Procure some inch board, out of which cut two sides, (Fig. 101, A A A) slightly larger than the outline of the bed. Rebate them ⅛in. deep to the width of an inch all round, and also across where the ribs or stays *a a a a a* are to come. Then prepare one piece for the top (B) 4ft. 0⅛in. long by about 3⅜in. wide. We say "about," because the stuff in the sides may be full or bare in thickness, and we want the bed to measure 5in. over the sides when roughly boxed up, the finished width being 4⅜in. Prepare pieces likewise for the bottom, *b, b, b, b, b,* and of the same width as the last, also the cross ribs, of the same width, too. Nail or screw all together. Plane up the sides to 4⅜in. wide at the bottom (bottom from the moulder's point of view, really the top face of the lathe-bed) by 5in. bare at the top. Plane over the face straight and square with vertical centre of the bed—i.e., so that the taper in the sides is equal relatively to the top; shape the blocks that form the swell round the gap, and plane 1/16th taper at the ends of the bed.

The main body is now ready to receive its equipments. Make a print 4ft. by 1¾in. by ⅜in. and nail it upon the centre of the face (Fig. 102). (In reference to the apparent discrepancy between the width of the print here given and the width of the groove in Fig. 100, as also to other instances of the same kind, as 5¼in. depth of bed in Fig. 102, against 5in. in Fig. 100, let me remark once for all, that these are the usual "planing" allowances. If the bed is to be filed up, less than half this amount will be sufficient). Extend the width of this print *just over the intended gap* to 4⅜in. (Fig. 103, Fig. 102, *c c*), the reason of which provision we shall see by and by. Prepare the outer V-shaped strips to the sections (Figs. 104, 105), and wire on in place, Fig. 102, *a a*. The outer lines in Figs. 104, 105, are the *pattern* lines, the inner ones represent the *planed* sizes. Make the fillet to section (Fig. 106), planing the straight portions, and cutting the curved parts round the gap with gouge and chisel, and nail or screw in place (Fig. 100, *a a*; Fig. 102, *b b*.) The strips D D D round the gap

must, however, be wired on. The two facings for the standards 5½in. by 3⅜in. by ¼in (Fig. 100, *c c*), complete the pattern.

For the first core (Fig. 100, plan), frame up a box 1ft. 5½in. by 4in. by 5⅜in. (Fig. 107). This is long enough to include the first and second ribs, and deep enough to include the print. Plane two strips 1ft. 5½in. by 1⅜in. by 1⅛in., equalling respectively length of box, depth of inner strip and print, and width of inner strip with planing allowance, and screw them against the sides of this box flush with its top edge (Fig. 107, A A). Prepare two cross bars ¾in. thick to the shape and dimensions indicated in Fig. 108, which represents a section of the box, looking towards the end, and screw in place (Fig. 107, B B). Prepare a piece 4in. by 3in. by ¾in., and fasten at one end for the standard facing, Fig. 107, C.

The next box is framed to 1ft. 4½in. by 4in. by in., and one end is made to follow the outline *the pattern (Fig. 109).* In the end next the *cross-bar similar to the others,* but 3in. deeper, is fixed (B). The guide strips A A, for the headstocks, as in the last box, will be required. The box for the third core (Fig. 110) will be 8in. by 4 by 5⅝, having strips A A, cross-bars B B, and facing for standard C; or the second box may be utilised after its core is made, by screwing a cross-bar in 8in. from the end next the gap, and putting in the necessary parts.

The gap box (Fig. 111) is framed to 6in. by 4⅞in. by 8⅜in. This, it will be seen, corresponds with the print in Fig. 103. Against the sides of box screw two blocks 6in. by 5in. by 7/16in. (Fig. 111, *a a*), to form the metal at the sides of the bed below the gap.

The shape adopted for the bed just described permits the use of a better type of saddle than the one described for use with a wooden bed. The upper portion may, however, be still retained. The views are self-explanatory. It will be observed that no provision is made in the saddle for rack or screw traversing. To go into these matters would involve more than the scope of the present paper will admit of. But there would be no difficulty in providing either scr or rack motions for the lathe as far as the mod fication of the rest is concerned.

Fig. 112 shows the saddle and transverse sli in plan; Fig. 113 sideways; Fig. 114 in fro A is the screw; B the nuts attached to the sadd by the screws C C; D the nut held in the tran verse slide, through the medium of which t motion of the screw is communicated to the slid E the stud for the longitudinal slide; F F turned bevelled groove to receive the tightenin nuts for the upper slide; G loose strip for tran verse slide, tightened up by screws H H; I the loose strip for the saddle, fastened by screv J J, and *set* by screws K K; L L slots-f T-headed bolts, for convenience of holding wo to be bored.

Taking the pattern of the saddle first (Fi 115), make the main plate 2in. thick, to dimensio given, framing the parts together either wi half-lap joints or by mortises and tenons; on a print, A, ½in. thick, to take out the reco for the transverse slide; screw on the strips B

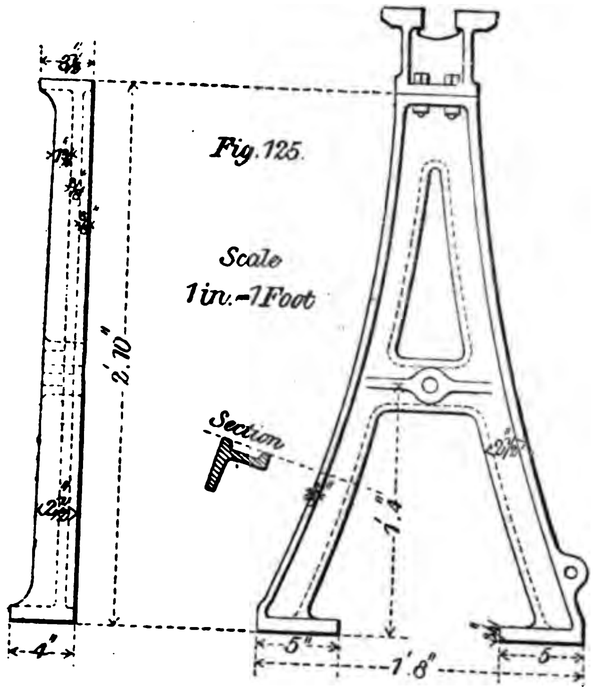

Fig. 125.

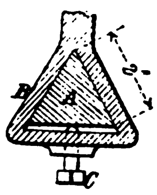

Fig. 127.

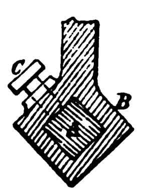

Fig. 128.

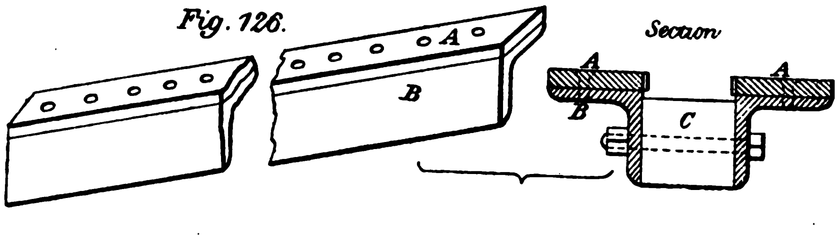

Fig. 126.

which embrace the lathe-bed, wiring on the Vee, which is cast in a piece with the saddle. Fig. 116 shows a section of the corebox, looking towards one end. By means of the curve *a* on the end cross bars of the box, the core is strickled to a corresponding shape for the purpose of taking out the recess underneath the traversing screw. The prints L L L L and their corebox M, shown in section, are for the ⊤-headed slots, shown in the three views of the rest. Fig. 117 is a half-size section of the loose Vee strip, I in Fig. 113, giving planing allowance.

Fig. 118 shows the pattern of the transverse slide, top and bottom faces respectively. The plate A is 5¾in. by 4in. by ¾in. (finished to ⅝in.) Upon this the circular face, with its print for the bolt recess B, Fig. 119, in section, is fastened. Fig. 120 shows the core box for this recess, in section and plan. A is a bottom board upon which a centre piece B is studded, and a ring piece, C, dowelled; the unshaded portion being the core space. Note that the width of core is given as $\frac{5}{16}$in. against ⅜in. width of groove on top of Fig. 112. This allows of the barest possible amount of skimming up in the lathe, the core being too small to permit of much turning allowance, neither is much necessary if the box be made truly. A slot will have to be cut in the casting, shown at M in Fig 112, through which to thrust the tightening bolts into place.

For the under face of the traversing slide prepare a piece of stuff 5¾in. by 1⅞in. by ¾in., and fasten on in the centre of the plate already prepared (Figs. 118, 121, B); on this wire the loose strip C, and nail the print D. Make core box (Fig. 122) jointed longitudinally, J J, and dowelled and recessed at sides A A, to receive the brass nut (Figs. 112, 113, D, and Fig. 123). The pattern for the loose strip G, Fig. 114, shown in section in Fig. 124, completes this part of the work.

The standard (Fig. 125) is suitably designed for the bed which we have described. The frame will be made with half-lap joints, and the ribs screwed upon it with $\frac{1}{16}$in. of taper on their inner faces. The ⅜in. ribs on the outer face simply relieve the heavy appearance of the casting.

Three forms of lathe-beds may be briefly noticed, which I have seen adopted. The first, Fig. 126, is made by riveting a piece of flat bar-iron, A, on a length of angle iron B, and planing or filing the face and the inner edge of the bar-iron true afterwards. Distance blocks, C, keep the cheeks duly apart. This is the best form of makeshift bed that I know of.

Another is simply a triangular bar of cast iron, Fig. 127A, planed or filed true, along which the poppet B slides, being tightened by the screw C. This answers for a light lathe.

The last consists of a bar of wrought iron, Fig. 128A, along which the poppet and rest slides, as in the last case. But the wrought-iron bar lacks rigidity, and the shape is not so well calculated to resist the shocks of turning work as the triangular form.

ON A NEW METHOD OF GENERATING ELECTRICITY.*

After referring to the researches of Deville and Troost, and the subsequent experiment of Graham on the penetration of hydrogen through red hot metals, the author describes experiments which he made with a view to constructing a voltaic cell in which occluded hydrogen should take the place of zinc. Cells were constructed by taking tubes of platinum foil, closed at one end, and connected with glass tubes by which hydrogen or other gases could be supplied to the interiors of the platinum tubes. Such a platinum tube could be held in the centre of an ordinary platinum crucible, which was intended for the other element of the cell. Various substances were fused in the platinum crucible at a red heat, and by connecting both the platinum tube and the crucible with a galvanometer by means of platinum wires any generation of electricity could be perceived. Several oxidising salts were tried without success, but by using glacial phosphoric acid at a red heat the author found a distinct production of electricity when hydrogen gas was conveyed into the platinum foil tube. The experiments being continued, it was found that a number of saline bodies in the fused state developed the electrical current with hydrogen, the chlorides of the alkaline and earth metals being quite as efficient as glacial phosphoric acid. It was found that the platinum tube containing hydrogen acted like a zinc plate in a voltaic cell, but it appeared that the hydrogen, after passing through the saline medium, also passed through the walls of the platinum crucible, and it was then oxidised. In order, therefore, to get good results it was necessary to maintain an oxidising atmosphere on the outside of the platinum crucible. A more perfect apparatus was subsequently made for carrying out these experiments, and by the use of this apparatus numerous substances were tested as to their transmitting capacities for hydrogen. Vitreous matters, such as glass, were found to make much better media than the alkaline chlorides. Even porcelain and earthenware were found to transmit hydrogen at a high temperature, under the peculiar conditions of the experiments. The use of glass as a medium made it possible to extend the researches in several directions, as oxidisable metals could be used in association with glass. The method usually adopted by the author was to take a glass tube of suitable quality, and to coat it internally with a metal, either in the form of sheet or as a pulverulent deposit. The glass was carefully fused on to this inner metal, whilst hydrogen was passed through the tube to prevent oxidation of the metal. Then the outside of the glass tube was usually covered with thin platinum foil. On connecting the inner and outer metals with a galvanometer and heating to redness, while hydrogen was supplied to the inside of the tube, the electrical phenomena were obtained with great facility. Nearly all metallic substances appear to be available for the internal coatings of these cells. These effects were easily reversible if a reducing flame was applied externally and air had access to the interior of the tube, as in this case hydrogen was supplied by the flame.

The quantity of electricity produced by this new method is proportionate to the amount of hydrogen diffusing through the apparatus; or, in other words, to the extent of metallic surface. The production of electricity also increases with the temperature. The electromotive force is, however, low. It was found by the author that the vitreous matters used for the cells were practically non-conductors of electricity of low tension if access of hydrogen was prevented, although they became good conductors when hydrogen was supplied.

The second part of the paper describes experiments in which the hydrogen in flames gives rise to electrical currents by acting on arrangements of glass and metal. A rod or wire of metal such as platinum or iron was covered with fused glass, and the glass was overlaid with platinum foil. On connecting the two metals with a galvanometer, and heating the cell in a flame, a current of electricity could be produced, which was due to the withdrawal of occluded hydrogen from the inner wire or rod by the action of an oxidising flame upon the platinum foil. Also a "reverse" current could afterwards be produced by the action of a reducing flame upon the platinum foil, hydrogen being then re-occluded by the inner metal. An experiment is also described in which a continuous flow of hydrogen was maintained through a cell having a fused vitreous medium by means of a Sprengel vacuum pump. In this case two concentric tubes of platinum were used, and the hydrogen was derived from a reducing flame, by which the apparatus was heated. The inner tube was connected to the Sprengel pump. By this apparatus a continuous current of electricity was produced. The author also describes some experiments which illlustrate the remarkable atomic force which hydrogen in flames exerts by reason of its great penetrative powers.

MADAN'S MODIFICATION OF DARKER'S SELENITE HOLDER.*

H. G. MADAN, of Eton College, has devised a modified form of selenite holder, which he finds preferable to the holder usually made.

The ordinary form of Darker's selenite substage fitting is well known; three films of selenite, giving retardations of ¼ wave, ¾ wave, and $\frac{5}{4}$ wave, respectively, are mounted in circular brass cells, which rotate in rings attached to a side arm, and can be thrown in and out of the field as required. This arrangement is perfectly effective, but it has two inconveniences: (1) that no means is provided for changing the films for others, such as Ackland's neutral tint film, or Klein's plate; (2) that when the selenites are in a position for use it is difficult to see, and impossible to tell by feeling, the exact azimuth of that direction in the crystal film, which is usually marked by opticians P A; i.e. the direction in which the retardation of one of the two rays behind the other is greatest, and which lies, of course, at an angle of 45° with the acute bisectrix, or "median line."

The arrangement described below is intended to avoid both these inconveniences.

The selenite films are mounted in cells of the shape shown in Fig. 1; a groove being cut in the edge of the cell before the handle A is soldered into its place. The holder is in the form of a ring, about 3-7ths of which are cut away, as shown in Fig. 2; the remaining part being quite sufficient to retain the cell in position, and yet allow it to rotate freely when it is "sprung" into its place.

Three of these holders are jointed to a side arm, so that they can be thrown in and out of use, as in the usual Darker's stage.

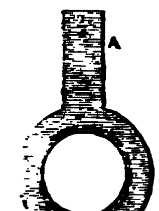
---

* Abstract of paper by J. A. Kendall, F.I.C., F.C.S., read before the Royal Society.

* *Journal* Royal Microscopical Society.

The handle A is made of such a breadth as to allow the selenite an angular movement in azimuth

Fig. 1.



of exactly 90°; which is, of course, sufficient for all modifications which it is capable of producing in a polarised ray.

Thus the various combinations of the films are obtained by merely moving the projecting handle 45° on either side of its central position—motions as simple and easy as those of a signalman in throwing over his levers for altering points and signals. In my own case, I have mounted the films in such a position that the acute bisectrix is in a line with the centre of the handle (Fig. 3). Hence, the plane of polarisation of the light being supposed vertical (i.e. at right angles to the length of a slide placed on the stage): (1) when the handles of the selenite holders are also vertical, the ray passes through the films without change; (2) When the handles are thrown 45° to the right hand, the maximum retardation due to the sum of the thicknesses of the films is produced: (3) When any one of the handles is thrown 45° to the left hand of its central position, the retardation due to that film is subtracted from that of the others.

Fig. 2.

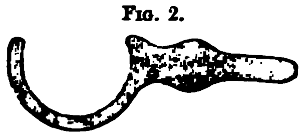


Fig. 3.

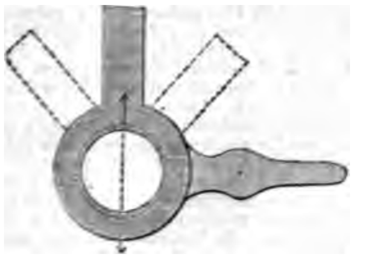

Thus it is easy to obtain any given retardation within the range of the series of films without removing the eye from the microscope. So, again, to obtain right-handed circular polarised light, the two thicker films are either thrown out of the field, or placed in the median position, and the handle of the ¼ wave film is thrown 45° to the right. To obtain left-handed polarised light it is thrown 45° to the left.

In my analyser cap a holder of somewhat similar construction is fitted for a single ¼-wave film, so that it is easy to analyse the light circularly, when desired.

If, for special purposes, an entire rotation of a film is desirable, it is only necessary to omit the handle, and mill the edges of the cell on either side of the central groove—in fact, I have several cells thus made. But I prefer the handle from its convenience in showing the exact optical position of the film.

I should like also just to call attention to the ease with which almost any microscope stand can be made to serve as a Nörremberg's polariscope for examining crystals under strongly convergent polarised light, in order to see the rings, &c., round the optic axis. All that is required is, to remove the nose of the main body, and screw into its place the usual system of converging lenses (which answers much better than any microscopic objective), the fourth lens of the system being fitted into the drawtube. A similar system of lenses is then fitted below the stage, in place of the condenser, and the crystal to be examined is placed on the stage; or, preferably, supported in a holder like Beck's opaque object holder, which allows it to be rotated.

Microscopes which, like Ross's newest pattern, have the fine adjustment separate from the main tube, and in which the stage can be swung to any angle, or removed altogether by simply loosening a screw, are especially adapted for the above fitting, since the upper lens system can be as large in diameter as the main tube.

The lenses I used were the ordinary "spectacle" lenses, including a pair of hemispheres, and the field is nearly as great as that of Hoffmann's instrument, just taking in the two axes of Brazilian topaz.

With such an arrangement, combined with the selenite stage, nearly or quite all the beautiful experiments given in Dr. Spottiswoode's little treatise on "Polarised Light," can be made.

It is more than a dozen years since I made the above addition to my microscope; and I am surprised that Nörremberg's lenses are not included among the usual "accessories" of (at any rate) first class microscopes.

A NEW THEORY OF LUNAR FORMATION.*

NOTICING the fact that there is a sequence in size in groups of craters, I was led to believe that this represented a sequence in time also. Hence I was led on from the inadequate explanations at present in vogue to believe that the rings are made of condensed vapour, snow, of a sort not necessarily exactly as ours, and that the solid ejecta piled to form the cones in the plain (beyond which the ejected favours fall) condensed as hail or snow, and circle, fountain wise, far beyond being in a vacuum.

Now, erosion is the great feature of our earth's surfacing, except at the poles, where the temperature is so low, and the surfacing is piled deposit. This struck me as the key to the surfacing on our moon. The general plan of surfacing is not cut out: it seems piled. Naturally, where there was neither air nor water (as such) a close study of this phenomena of piling up led me to wonder how it was done. It seemed to me self-evident that in such a group of deposited rings as Stofler (354 IV quadrant in Webb's map) the series in age or sequence and the series in size coincided to four places. In almost all other cases of interference, where one circle cuts another, the last is apparently always the smaller one.

Let us assume that the Moon and Earth are parts of one mass, and that the materials are not very dissimilar; that when separated each had a far larger atmosphere in proportion than we have now, and that from the far higher temperature the water was more or less suspended as steam or cloud. Now, as time passed on the moon cooled down to, through, and past the earth's present state. Then a time would come when we should see our polar and arctic phenomena, absence of life, and general similarity to what we see on the highest terrestrial elevations. At this time we should have simply a deposit of solidified snow, showing angular formation in places and in others the reverse, where the snow can lie for ages unchanged under a vertical tropical sun. In the case of the Himalayas it does so, the conditions necessary being bright above the snow line on a greatly attentuated vapour. We can further understand the gradual encroachment of the arctic icefields till they meet and case the earth in ice, below which in the oceans there would still be enormous reservoirs of water at 32°. The decreasing temperature would necessitate contraction of the globe, and the ice-shell would be ruptured, and large volumes of water emerge and flood the ice crust, level it, and being repeated it might gradually raise the level, and thus large raised flats may have been caused. Most of the lunar surface that we see is actually made of the lunar oceans, forced through a frozen solid surface and deposited outside till there was no more water or vapour to come out. The later ejections would only be able to melt a small cavity or crater hole, and pile the precipitated vapour close round. This would explain the otherwise difficult problem as to what becomes of the portions of rings effaced. They are melted away, and thus also the smaller circles may at times be the deeper ones. While the oldest of these circles is at the snow line, the second or smaller may have been formed below the snow line, but the deposit piled up to the snow line, and in the same way, as the cooling went on, the third, the smallest and deepest would be formed. In the case of large lunar rings the vapour rises from either an orifice or off a water basin that surrounds one, and the vapour is deposited in a circle around. If there were winds on the moon we should not see the deposit as a true ring, and if there was a steady and slow drift in an extremely rare atmosphere we should see elliptical craters. The objection that snow would appear as dazzling white is met by the fact that meteoric dust falls on our polar regions even in such a quantity as to be visible to the eye. Our snow is renewed, but the lunar snow is permanent. The long lines of tiny craters would be du to the vapour rising through faults. The concentric formation in the walls of the large walled craters is obviously a formation from a centre; it shows a formation from a centre as surely as the earth's polar ice-caps show the reverse—i.e., from a circle to a centre. The size of the walled plains seem to preclude the formation of a ring from solid rock ejected. They would seem more like frozen precipitated vapour, deposited while the contained sea was near and just below the line of perpetual ice.

In the second letter, speaking of the circularity, Mr. Peal says:—"It is traceable from the smallest craterlets to large ones, as Tycho, Copernicus, &c., from faint little rings laid as it were on a level surface, or larger, as Stadius, to great walled plains, with or without central cones, as Plato, Clavius, and still larger in S. Iridum, Mare Crisium, &c., and even the Mare Imbrium is like the S. Iridum, circular (though not complete); thus from the smallest to the largest the lunar features are circular. As regards the explosive theory, it seems incredible that in such craters or circles as *Plato*, Archimedes and Stadius that the explosions should result in such regular formations and leave the inclosed plain so destitute of signs. Again, such forms as the S. Iridum, Fracastorius, &c., are valuable on my theory. On looking at the moon with a low power, one cannot resist the conviction that the Mare Crisium is simply a larger instance of the S. Iridum or Plato; the greatest elevations are closest to the circle, and the surface descends thence downwards. The cause that formed the S. Iridum and Plato seems also to have formed the Mare Crisium. 1st, it is circular; 2nd, the inclosure is a plane on the surrounding material, is highest at or near the edge, and descends thence outwardly; the colour of the inclosure is different and darker than the surroundings. The mists seen at various times and by various observers may be the last trace of the action I have tried to depict."

In a third letter he explains that the forms of the S. Iridum, Fracastorius, &c., were caused by the removal of water and its deposit on land around, all that fell seaward being again remelted, and the piling could only thus take place landwards.

The theory explains:—

(1). The sea bottoms being apparently bare.
(2). The formation of S. Iridum and similar objects.
(3). The excavation and piling around of the matter removed from the cavity.
(4). The rings being concentric, and having several cones to one ring, and not a ring for each cone, as should be the case.
(5). That the later rings removed the water of the older where they interfere, and they are smaller and deeper.
(6). The evenness of the floor in many cases, since it is frozen lake surface.
(7). The craterlets being heat vents that melt out small cavities from which the moisture is removed and piled around, may form anywhere all over the ice-surface, and on the walls of the large rings, seldom seen on sea bottoms, though likely where any shallow sea is frozen.
(8). That as the energy slowly dies down, the heat is less, and the water and vapour forced through by contraction of the crust through cold, does not form a lakelet or crater, but is piled up in a lump or mound.
(9). That vents along a fault may cause a series of little craterlets, and that if the vents are small, moisture oozing will pile as a rule, either above the level of the fault opening or below it, and be bright since it is most modern, and it may, as a fault, pass through crater walls.
(10). That if there is sufficient inclination and time, the material may form glaciers, appearing like lava flows.
(11). That (most important of all) the whole phenomena form a series denoting expiring energy, and not violent and intense heat.

COAL GAS AS A LABOUR-SAVING AGENT IN MECHANICAL TRADES.*

By Thomas Fletcher, F.C.S.

GAS, as a fuel, is an absolute necessity to the economical carrying out of many commercial processes. It is often used in the crudest and most costly way. A burner may be perfect for one purpose, yet exceedingly wasteful for another, and however good it may be, an error of judgment in its application may lead to its total condemnation. An excess of chimney draught, in cases where a flue is necessary, may pull in sufficient excess of cold air to almost neutralise the whole power of the burner, unless a damper is used with judgment. With solid fuel, an excess of draught causes more fuel to be burnt, but with gas, the fuel is adjusted and limited; there is no margin or store of fuel ready to combine with the excess of air, which, therefore, by its cooling power, lowers the amount of work done. The power of any burner, for any specified purpose, depends not only on its perfection, but to a far greater extent on the difference in the temperature of the flame, and of the object to be heated. For instance, if a bright red heat is required, it is not possible to obtain this temperature economically with any burner working without an artificial blast of air, the difference between the temperature of the flame, and that of the object heated, is too little to enable the heat to be taken up freely or quickly, and the result is a large loss of costly fuel. If we want to obtain high temperatures economically, an artificial blast of air is necessary, and the heavier the pressure of air, the greater the economy. On the contrary, low temperatures and diffused heat are obtained best by flames without any artificial air supply.

---

* By S. E. Peal, of Sibsagar, Assam. Communicated by the author to the Liverpool Astronomical Society.

* Extracted from a paper read before the Society of Arts.

For such purposes as ovens, disinfecting chambers, japanners' stoves, founders' core drying, and similar requirements, the best results are obtained by a number of separate jets of flame at the lowest part of the inclosed space, and the use of either illuminating or blue flames is a matter of no importance, as the total amount of heated air from either character of flame is the same. If there is any preference, it may be given to illuminating flames, as the proportion of radiant heat is greater, and this makes the average temperature of the inclosed space more equal; but, on the other hand, may be considered the greater liability of the very fine holes, necessary for illuminating flames, to be choked with dust and dirt. This may, to a great extent, be obviated by using very small union jets, and setting them horizontally, so as to make a flat horizontal sheet of flame. Burners placed this way are practically safe from the interference of falling dust or dirt, but not from splashes. Falling dirt or splashes must always be considered in the arrangement of any burners, and the ventilation must be no greater than is absolutely necessary for the required work. In cooking, this limit of ventilation may be exceeded, as most things are better cooked with a free ventilation, the extra cost of fuel being well compensated for by the better quality of the result.

Where an oven or drying chamber is used continuously, it should be jacketed with slag wool or boiler composition, but for many purposes this is no advantage. As an example both ways, I will instance the drying of founders' cores where there is only one blow per day. The cores of an ordinary foundary can be dried by gas in a common sheet-iron oven in about half an hour; any accumulation of heat after that time would be useless, and a jacketed oven would be of no advantage.

For the disinfection of clothes in vagrant wards and hospitals for infectious diseases, on the contrary, a continued heat is necessary, and in this case the accumulation of reserve heat, which takes place slowly in a jacketed oven, becomes of value, as the gas can be terned low or out, and the ventilators closed, insuring a more complete disinfection with a much smaller gas consumpton. Where an oven or heated chamber is much used for periods of over half an hour at once, a non-conducting casing pays well by reduced gas consumption.

For albumen and glue drying, leather enamelling, tobacco drying, and purposes where a large space has to be very slightly and equally warmed when the weather is unfavourable, steam pipes are generally used, but, not being always available, an exceedingly good arrangement may be made by placing at intervals in the room gas burners, of any construction, close to the floor, and surrounded with a sheet iron cylinder, say, 2ft. or 3ft. high. The tops of these cylinders must be connected throughout with a fairly large flue, which will take the products of combustion from the whole, and this flue must be carried either horizontally, or with a slight rise, so as to utilise all the waste heat. The reason for having a number of stoves at intervals is that the heat in a flue will not carry, for any useful purpose, more than about 8ft. or 10ft., and a stove would give an irregular temperature in any except a very small room. If all are not used at once, the flues of those not in use may be closed by a damper to prevent down draught. The use of hot-water pipes heated by gas may also be occasionally advisable, but, unless for some special reason, it is much more economical to use coal or coke, as the bulk of water makes an exceedingly good regulator, and makes a fire practically as steady and reliable as gas, thus superseding the more costly fuel.

For one of my own purposes I need hot-water pipes, having very little variation in temperature night and day, and using coke for economy's sake, I get a regular temperature by heating a large quantity of water, about 200 gallons, with the fire, and inclosing this in a tank jacketed with slag wool. My circulating pipes run from this tank, and a practically steady temperature, night and day, can be obtained with the most irregular firing, and occasional extinction of the fire for several hours at once.

For the heating of liquids, the greatest economy is to be obtained from one single flame, of as high a temperature as can conveniently be obtained, and the flame must be in actual contact with the vessel to be heated. In jacketing vessels, to prevent draughts, care must be taken that the jackets do not cause currents of cold air to rise rapidly up the sides of the vessel, and so cool it. If this is the case, the use of a jacket, instead of being an economy, is a positive expense, and waste of heat. Many processes, such as making oil and turpentine varnishes, require a heat under instant control, and in these, the use of gas is an important matter, as the loss and risk of fire are very serious elements of expense, more especially in small works where special and costly preparations for contingencies cannot be afforded. I have here, Fig. 1, a burner which, for its power, is, perhaps, the most compact, and gives the highest temperature of any burner yet known, and it is easily made in almost any size; it has, I think, many special advantages. The use of gauze, which is its only weak point, is more than compensated for by the very high duties obtained in practice with it, owing to the compactness and concentration of the heat obtained.

In such processes as the roasting of coffee, chicory, grain, &c., a diffused heat is necessary, but of much greater intensity than can be obtained with economy from heated air. In these cases the application of a direct flame is necessary, and it may be in actual contact with the substances to be heated, provided these are kept in constant and rapid motion.

The use of a revolving cylinder brings in complications with any burner which is supplied with gas at ordinary pressure without any artificial air supply, as the currents of air caused by the motion of the cylinder interfere with the satisfactory working of any burner, and the air supply must be either protected from draughts and irregular air currents, or the air must be applied artifically from some independent source. One exceedingly good way of making any burner work, independently of the currents caused by a revolving cylinder, is to apply the flame inside the cylinder at the centre, making the substances to be heated to fall in a continuous stream through the flame. This system is not applicable to fine powders, or sticky substances, as it necessitates the perforation of the cylinder, to allow of the escape of production of combustion.

For this class of work, a very concentrated heat is not desirable, as a rule, and a slit, or perforated, burner is preferable. Of this class of burner I have one which is not only new in its constructive details, but has great and special advantages for many purposes. It resembles a number of ordinary furnace bars (Fig. 2) with this difference, that each bar is a burner; in fact, it is an ordinary furnace grate, which supplies its own fuel. With the usual day pressure of gas, = 1in. of water, this burner will, at its maximum power, consume about 100 cubic feet of gas per hour, per square foot of burner surface, and as it can readily be made almost any form or size, its adaptability for a great number of uses is evident. I have made it in many sizes and shapes, to give flames from ½in. wide by 5ft. long, to large square or oblong blocks. By applying a blast of air at the ordinary gas jets, and supplying the gas by a separate pipe, or series of pipes, below the open end of the burner, this can be converted into a furnace of extraordinary power. It is quite possible to burn as much as 2,000 cubic feet of gas per hour, per square foot of burner surface, producing a heat sufficient to fuse any ordinary crucible. You see its power when I place a bundle of iron wire in the flame; it is, in fact, a concentration of hundreds or thousands of powerful blowpipe flames in one mass. It has also this advantage, that with a blast of air it will burn and work equally well any side up, and the flames can therefore be directed straight on their work without loss. It is, in one form or another, almost a universal burner, as it can be readily adapted to almost any purpose, from tempering a row of needles to making steam for a 200 horse-power steam-engine. It is easy to make, easy to manage, practically indestructible, and for commercial purposes, has, I think, a general adaptability which will bring it, in one form or another, into almost universal use. I may say that when we are in a special fix, this has in every case landed us out of the difficulty.

For heating large plates of metal equally, for drying paper impressions for stereotypers, hot pressing hosiery, crumpet baking, working up plastic masses which can only be worked hot, and work of this class, a number of separate flames equally diffused under the whole surface of the plate are necessary to equalise the heat, unless the plate is very thick, and these are better if produced by a mixture of gas and air, but in heating wide plates one difficulty must always be remembered, the burnt gases from the centre flames can only escape by passing over the outer flames, and therefore a space must be left between the top of the flame and the plate, or the outer flames will be smothered and make a most offensive smell.

In hosiery presses, bookbinders' arming presses, and many others, the top plate also requires to be heated. The best way to do this is to use a number of blowpipe flames directed downwards. In many cases the supply of air under pressure is a practical difficulty and objection. This is overcome, to a certain extent, by the use of a thick upper plate with a number of horizontal holes, into which a Bunsen flame is directed. In every case I have seen, without one single exception, the holes are either too small, or the burner is placed too close, and the consequence is that the gas, instead of burning inside the holes, as it should, passes through partially unburnt, and is consumed at the opposite end, where it is absolutely useless, the flame not being in contact with or under the surface to be heated, and therefore doing no work. In hosiery presses this is a great objection, as the holes are so long that an equal heat is simply impossible, and the only remedy is to use a blowpipe flame, which forces sufficient air in with the gas to insure combustion where the heat is necessary. The same remark applies to crape and embossing rollers.

Sometimes a plate is required to be heated to a high temperature in one confined spot, and, as an example of this, I may take the blueing of the hands of watches. For this purpose I have made several arrangements, and perhaps the best is a thin copper plate, bent down at one side to a right angle. In this angle underneath is directed a very fine blowpipe flame on one spot, and the hands are passed singly over this spot until the colour comes, when they are instantly pushed over the edge (Fig. 3.) For the blueing of clock hands a larger and more equally heated surface is required, and this can be obtained by a small powerful burner without a blast of air, using a rather thicker plate to equalise the heat. The same arrangement may be used with advantage for tempering small cutters for ornamental turning, pen-knife blades, &c., and in these cases the cooler part of the plate is of great value, as it enables the thicker parts to be slowly and equally heated up; the application of a mechanical arrangement to pass the articles to be heated, in a regular succession is a matter easily managed.

It is now a simple matter, owing to recent researches in the theory of heating burners, to obtain flames of any power without practical limit, which, without any artificial air supply, will do all which is necessary in this class of work, and the required arrangements are exceedingly simple.

We may now consider the heating of blanks for stamping, hardening the points of spindles, finishing the ends of umbrella tips, and work where a small article, or a small part of any article, has to be heated to a high temperature with speed and certainty. For these a long and narrow flame is necessary, and I may mention that in cases where a high speed of delivery is required, and a small part only has to be heated, such as, for instance, in the hardening of the points of spindles for cotton machinery, I have made burners giving a flame of exceedingly high temperature only ¼in. wide and 5ft. long. This flame is produced by the assistance of a blast of air, and is of sufficiently high temperature to fuse the spindle in a few minutes.

The points only project over the flame, and the spindles are carried mechanically at such a speed that at the end of the 5ft. traverse they are red-hot and drop into water. More than one hundred are in the flame at once, lying side by side.

For heating blanks for stamping, the furnace bar-burner (Fig. 4) is perfectly suited, and in this work the shoot supplying the blanks to the machine should be made of two fireclay sides, with an opening for the flame between the shoot and flame being placed at a sharp angle, to prevent risk of the blanks sticking or overriding each other. A blowpipe may also be used with good effect, as shown in Fig. 5, and in many cases it is preferable and much easier to manage.

In some cases the direct contact of the flame would spoil the articles to be heated, and instead of the arrangement mentioned a tube of iron, fireclay, or other suitable material is heated, and the articles are passed through it (Fig. 6). This system of continuous feed, through a tube, has been applied to the firing of small articles of pottery, and might possibly be well adapted, amongst other things, to the production of gas-burners.

Where the contact of air with the heated articles is injurious, many plans have been tried to keep the ends closed as much as possible, but I believe no more perfect and simple seal against the admission of air can be devised than to turn a jet of pure gas, unmixed with air, into each end of the tube. This is an absolute seal against the entry of oxygen in an uncombined state; free oxygen cannot exist at very high temperature in the presence of coal gas.

For many trades there is a demand for hardened and tempered steel wire, either round or flattened, and the production of this has led to many attempts to obtain a satisfactory continuous process. The common method now, which is worked as a "secret" process by most firms, is to pass the wire through a tube to heat it, as already described, and to run it direct from the tube through a hole in the side of a box filled with oil, the hole being packed with asbestos, to prevent leakage; from this it is passed through another similar hole on the opposite side, either over a plate heated to the right temperature or over a narrow open flame of sufficient length and power to give the correct heat for tempering.

Where absolute precision is necessary, the gas

supply must be adapted by an automatic regulator on the main, to prevent the slightest variation of heat. Once adjusted, the production of flat and round spring wire by the mile is an exceedingly simple matter. It is quite possible to obtain absolute precision in temperature by a proper adjustment of the gas pressure, and as this is, for tempering steel articles and some other purposes, a matter of great importance, it is worth some consideration. No pressure regulator alone will give an absolutely steady supply; but if we put on first a regulator, adjusted to the minimum pressure of supply, say 1in. of water, and then fix another on the same pipe, adjusted to a slighly lower pressure, say $\frac{8}{10}$ths of an inch, the first regulator does the rough adjustment, and the second one will give an absolutely steady supply, providing always that the regulators are both capable of passing more gas than is likely to be ever required. No regulator can be relied on for absolute precision if worked up to its maximum possible capacity.

The thousands of uses to which blowpipes are adapted are so well known, that they need no mention, except the curiously ignored fact that the power of any blowpipe depends on the air pressure. A compact flame of high temperature cannot be obtained except with a heavy air pressure, and the ignorance of this fact has caused an immense number of unexplained failures. Many people think that one blower is as good as another, and expect that a fan giving a pressure equal to, say, the height of a 2in. column of water should do the same work as a blower giving the pressure ten to twenty times as great.

Since the conclusion of my experiments on the theoretical construction of burners I have found that the high-power burners, previously described, are capable of heating a crucible equal in size to *their own diameter to bright* redness without the *assistance of a chimney*, provided the crucible is *protected from daughts* by a fireclay cylinder.

This is an important point, as it renders the production of a continuous bright red heat a matter of the greatest ease, even in crucibles of a comparatively large size. Where the heat is steady, and certain not to rise above a definite point, it can safely be used for such purposes as hardening penknife blades and other articles which are very irregular in thickness, the thin edges not being liable to be burnt or damaged by over-heating.

For the highest temperatures air under pressure is a necessity, as we require a large quantity of gas burnt in as small a space as possible with the maximum speed, and, given this air supply, we are very little hampered by conditions, as an explosive mixture may be blown through a gauze into a fireclay chamber, closed, except so far as is necessary to allow the escape of burnt gases. The speed of combustion is limited only by the supply of air and gas, and increasing these these there is no practical limit to the heat which can be obtained. Where we have to do with the reduction of samples of refractory ores, testing the comparative fusibility of different samples of firebricks or alloys, &c., the use of an explosive mixture blown into and burning in a close chamber is invaluable, and the ease and certainly with which any temperature may be obtained has led to great discoveries, and the revolutionising of many commercial processes. Recent experiments have proved that by a modification in the form of the well-known injector furnace, an enormous increase of temperature may be obtained. I have, in actual work, obtained the fusing point of cast-iron in two minutes, starting all cold, and have fused every furnace casings I have yet been able to produce. If infusible casing can be made, I think I am not overstating facts in saying that any temperature required can and will eventually be obtained with the greatest ease. What the limit is I have as yet not been able to discover.

There is one more application of gas, as a fuel, which, discovered and published by myself some two years ago, has yet to become generally known, and in some special processes may prove exceeding valuable. This is the addition of a very sma quantity of coal gas, or light petroleum vapour to the air supplied by a blower or chimney pull furnaces burning coke or charcoal. The insta and great rise in temperature of the furnace, and th greater stability of the solid fuel used, are extra ordinary. This is, in fact, a practical application the well-known "flameless combustion," the on signs that the gas is being burnt being a great ri in temperature and a decreased consumption of th solid fuel; in fact, if the gas is in correct proportio the solid fuel remains unburnt, or nearly so, in sp of the high temperature. In cases where a sudd rise in temperature is required in a furnace, where the power is deficient, this method of supp menting and increasing the heat will be found very great service, and processes liable to checked by making up a fire with fresh fuel can carried on without check, even after the solid fu has almost entirely disappeared.

That a solid fuel is quite unnecessary I will pro in a very simple manner, by burning a mixtu of coal gas and air without a flame, in a bundle iron wire. The heat is sufficient to fuse the wroug iron with ease, and the glare inside the bundle wire is painful to the eyes. The same result cou be obtained by a pile of red-hot lumps of firebric and the same heat obtained also without a trace flame.

Of the special trades which have come under m observation I have only had time to mentio few. It appears to me that there are very f manufacturing processes of any kind which coul not be simplified by the use of gas as a fuel.

The first of the permanent caissons for the For Bridge, 70ft. in diameter, is now being put togeth on the beach, where it will be riveted up b hydraulic power, and then floated into position.

PIPES, GREEN SAND CORES, AND HOLLOW PIPE PATTERNS.*

THERE are few foundries that do not in some form make more or less pipes, and it is astonishing to note how much faster the same class of pipe work will be made in some shops than in others. This is mainly due to the difference in the facilities and rigging. In some shops a man may have to work harder to make one pipe than he would in others to make four, and as a general thing the shop that could turn out the four would require the least skill. Shops that produce such castings the slowest are, as a general thing, the ones that have the fewest to make, and therefore cannot afford the expense of getting up labour-saving rigging. There are times when a little outlay in some shops would be the cause of procuring much work, that in the end might result in the manufacture of a good paying specialty.

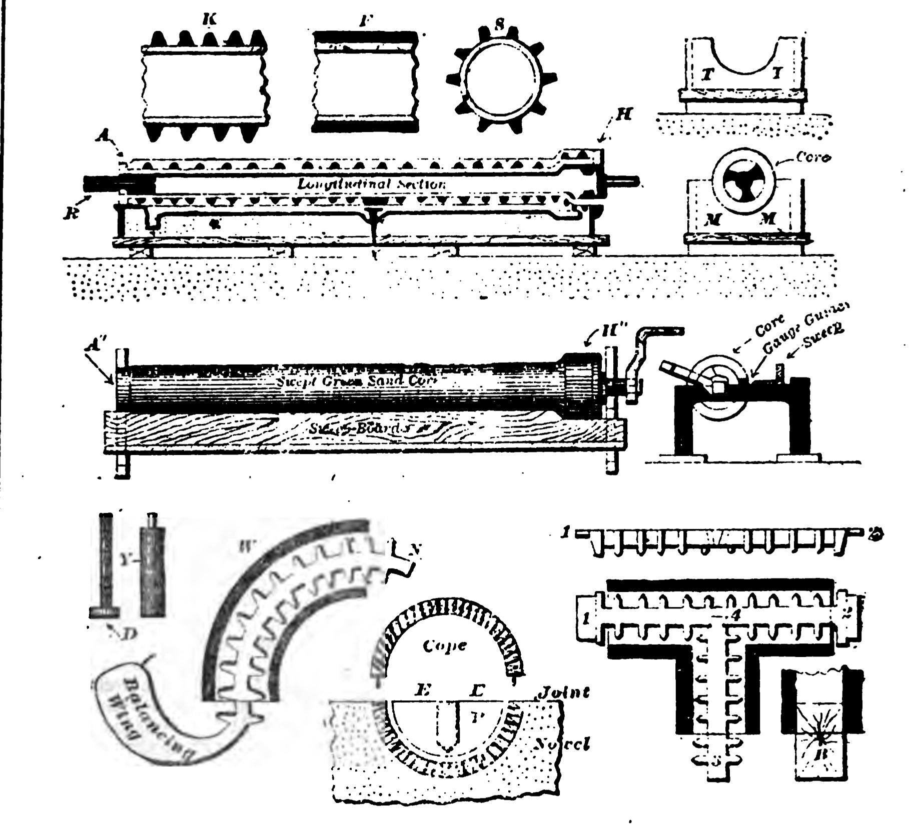
The general jobbing shop way is to make solid dried sand-pipe cores. The extra expense made thereby is the requiring of flour, and sometimes beer or molasses to mix with the sand. It also requires much labour to make them, fuel to dry them, and the loss of sand, and after all the time, labour, and expense we do not produce a perfect, round even core.

A plan practised in some shops that make a specialty of green sand-pipe castings is as illustrated in cut, showing the sweeping of a green sand core. This style of core is sure to produce a round hole, and with rigging properly gotten up one man can make a large number of cores in a day. The sizes of pipe generally made by this plan range from 3in. to 12in. In making the core arbors there are two plans adopted. One is to cast arbors having prickers, and the other ribs, upon their surface to assist in holding on the sand. To show what is meant by ribs, the sections F and S are given. At K, and in longitudinal sections of core, prickers are illustrated. As a general thing the ribs are used for the smaller sizes of arbors, on account of their making the arbors stiff, thereby preventing the core from springing up and shutting off the thickness of metal when the mould is poured.

The larger arbors are in diameter, the more resistance to springing they have when moulds are being poured, so that arbors over 5in. in diameter can generally be made stout enough without the ribs. For holding the sand prickers are to be preferred. The ribs, as it were, separate the sand into sections, whereas the prickers keep it together more in one body. The larger in diameter the longer can pipes be made. A foot pipe would be some 9ft. long; a 3in. pipe 4ft. long, and sizes between in proportion. Of course the stiffer arbors are made the longer they can be. Were chaplets used with this class of cores, as with dry sand cores, they could be made much longer. There is a way whereby chaplets can be used with some green-sand cores. That is to have a knob about 1in. in area cast or riveted to the arbor as above the chaplet X. This spot being even with the surface of core rests upon the chaplet, thereby causing iron and lead to come together. For the cope a small body of sand is taken out of the core and some small plates or washers inserted, the top surface of which had better be kept ⅛in. or so below the core surface. The space around these washers or nuts is then filled in and the core then made as smooth as the rest of its surface. Upon the top of the inserted pieces the cope chaplet rests. In so chapleting cores care is required, for should the chaplets come otherwheres than intended, the core would be bursted, and the casting, as well as the arbor, most likely lost. With such work exact measurement and fittings are required. With large diameter pipes there would be danger by thus chapleting of bursting the casting, on account of the knob X and the pieces above it, making a brace that would prevent shrinkage. Sometimes there is no danger of the core springing downwards, but there is a tendency to raise. When the lifting strain of the fluid iron comes upon it, in such cases as this, the bottom requiring no chaplet, the knob X could be upon the cope side, and the cores thereon be chapleted down, casting the pipe by having a chaplet only on the cope side.

The reason for using the washers or loose plates instead of a solid body being secured to the arbors, as above X, is to allow the arbor to free itself. Were the top the same as the bottom there would be immovable iron to iron. By having loose washers or plates the jarring of arbor soon causes it to be free, thereby letting it come out.

Core arbors should be well perforated with small holes, to allow the gases to escape. The thickness of sand upon arbors ranges from ⅜in. to 1in. The more nearly dry the sand used the better. In sweeping up a core, the process generally is to touch the arbor with clay wash or water, and after being set upon the horses the sweep board is set, sand is packed by hand upon the arbor, after which, with a man turning slowly, the sweep board is lightly pressed forward until it strikes the gauge guide which gives the diameter wanted. The arbor ends, A H, can be used to give the diameter, but having the core gagued independently of the arbor is to be preferred, as the friction of the turning will wear away the guide and also more or less vibrate the arbor, thereby often causing the sand to drop.



A point that here might be mentioned is that the less sleeking done to pipe cores the better. In fact, it is best not to sleek them at all, leaving the surface as it is swept, as the metal lays more kindly to the core.

In casting the larger sized pipes, it is essential that the arbors should have reliable bearings. 3in. up to 4in. pipes could be cast by having sand print bearings, but above this last size the arbor ends, A H, would be better if turned up true, so as to exactly fit the flask iron ends, as shown at M M. The cut T T shows the end without the core in. The arbors being true, the flask ends would of course require to be the same. By having arbors set in such bearings it is evident that the core will be kept central, and that its weight cannot sink it down, or the liquid iron raise it up; that is, as far as the prints are concerned. It might be well to mention that the pattern prints must fit into the flask ends when moulding the pipes, in order to have the mould central with the flask ends. In making arbors having such iron-end bearings, one, if not both, should be made smaller that the inside of intended pipe, so they may be readily got out of the castings.

The longitudinal section of mould shows a flange on one end and a socket on the other. This is only to illustrate the idea that either kind can be made. In the smaller sizes of pipe it is not necessary that the arbors should be larger at socket end, as shown at H. If the arbors are straight their entire length, and the sand reasonably tough, the little extra thickness required to form the socket will hang.

The plug seen at R is inserted for the purpose of lifting the core. Where arbors are large enough to admit a trunnion being riveted on, as seen opposite R, it is advisable to do so, as they can be revolved easier. Revolving arbors, by having their whole diameter turn in a bearing, as seeen at A, cause much friction.

The cuts of elbow and branch pipes illustrate the making of pipers with hollow patterns, they being the same as the castings wanted. At E E is shown a sectional view of the pattern. The nowel having been rammed up, the core arbor P is then set in and rammed up. The cope part of pattern is then set on, and sand tucked in. The joint having been made, the cope is rammed up, and after being lifted off the top pattern is drawn. By taking hold of the arbor handles, Nos. 1, 2 and 3, the core is lifted out; the bottom pattern is then drawn and the mould finished. The core is then set back and cope closed. The end of arbor at No. 3 is of a style different from Nos. 1 and 2. Arbors as at Nos. 1 and 2 are handy for small pipe. The arbor is set on the mould board, and the nowel half of the pattern over it, and the nowel is rammed up and turned over, the arbor forming its own print. This style is not recommended for heavy cores, as it does not give print enough to hold up very much weight.

The arbor as at No. 3 is of the same form outside the pattern as it is inside. To form prints for such arbors, with hollow patterns, there could be half round blocks, as shown at plan B, rammed up with the nowel half of pattern, and then when the nowel is rolled over draw out the blocks. This would leave prints formed ready to set in the arbors.

The quarter-turn pipe shows the plan of an arbor made so as to balance the core, the balancing wing projecting beyond the mould preventing the back, W, from sinking down as it would were both ends of arbor the same as at N and the back nut chapleted. This style of an arbor can, of course, be operated as regards rolling over and print making the same as the T arbor described.

At Y is shown a core rod and core made upon it. The head D admits of the core being lifted vertically, and also is a support to the core if rested upon its end. This class of green-sand cores can be used vertically or horizontally, and for pipes about 1ft. long, 2in. or 3in. in diameter, where their manufacture is to be made a specialty, they are worthy of consideration. The cores are rammed in a box endwise, and require to be vented, for which, in some cases, it might be well to have two or three vent holes drilled through the head D.

Green-sand cores, as a general thing, require more or less rigging, which is one reason why more shops do not use them. The holes formed by green-sand cores, as a general thing, for smoothness and being true, surpass those made by dry-sand cores, and generally thinner casting can be made with green-sand than with dry-sand cores. The making of green-sand cores often requires much skill. There are many cores being made of dry sand that could be made of green sand, but, like many other things in moulding, it often requires practical experience and good judgment to decide the feasibility of making them.

The Skrivanow Battery.—According to the *Electrician*, this battery, as used to supply current to the headlights of the ballet girls in *La Farandole*, at the Paris Opéra, is composed of the following elements:—A plate of zinc and chloride of silver wrapped in parchment paper, constitute the electrodes, and these are plunged in an alkaline electrolyte. The whole is inclosed in guttapercha cells. The size of the battery is 5 centimetres high, 6 centimetres wide, and 15 millimetres thick. The manner in which these batteries are fitted on the dancer is very ingenious. The cells used are arranged in the buckles of a girdle round the girl's waist, the real fastening being at the back. The wires are led round to the back, and then pass up under the hair to the ring which fits on the top of the head and carries the lamp and glass star.

SCIENTIFIC NEWS.

THE death of Professor Ernst Friedrich Wilhelm Klinkerfues, director of the Observatory at Göttingen, was briefly announced last week. He was born at Hofgiesmar, in Hesse Cassel, in 1827, and having been connected with the Göttingen Observatory for several years, he succeeded Gauss in 1856 as director. Prof. Klinkerfues was the discoverer of several comets, his first being III. of 1853, and his last [illegible]. He was a voluminous contributor to the *Astronomische Nachrichten*, and to other German periodicals, and will be also remembered as an inventor of several ingenious instruments. It is stated that pecuniary embarrassments were partly the cause of the rash act which terminated his existence. Prof. Klinkerfues was elected an Associate of the R.A.S. in 1882.

At a general meeting of the Royal Irish Academy held last week, a paper by Mr. J. E. Gore, F.R.A.S., was read. It contained a list of 190 variable stars, accompanied by an elaborate series of notes upon the more remarkable. The periods of most of the stars have been determined with an approach to accuracy. The communication was referred to the Council for publication. At the same meeting, Mr. W. De V. Kane, M.A., read a report on the Lepidoptera of the S. and S.W. coasts of Ireland. Prof. O'Reilly read a communication on the main lines of jointing observable about Dublin, in which he concluded that they clearly pointed to earthquake ruptures of the earth's crust.

Mr. Clement L. Wragge has, we understand, established himself near Adelaide, and has fitted up an observatory, where he will carry on certain planetary and solar work in conjunction with an elaborate record of meteorology. The telescope is a fine equatorial by Wray, having an aperture of 4½in. Mr. Wragge will have the help of a trained assistant to carry on the work in his absence.

Prof. Sir W. Thomson, who has been made a Knight of the Order Pour le Mérite for Science and Art by the Emperor of Germany, has, according to the American papers, accepted an invitation to deliver a course of lectures at the Johns Hopkins Observatory in October next.

Prof. Langley, of the Allegheny Observatory, has been interviewed by a reporter about the sunsets, and has expressed the opinion that there is not only no antecedent improbability that the volcanic eruptions were the cause, but that they are the most likely cause we can assign. Prof. C. A. Young, of Princeton, says that the volcanic theory seems to him to be the true explanation.

The fluctuations of the barometer, as observed at Edinburgh on Saturday, the 26th of January, appear to have been the most remarkable yet recorded for that neighbourhood. At 9 a.m. the barometer stood at 28·934, and fell steadily until at 10 p.m. it gave the remarkably low reading of 27·451, which is the lowest properly observed reading ever noted in Edinburgh.

During the gales of the 26th and 27th ult., unprecedented wind pressures were experienced at the Forth Bridge Works. According to Mr. B. Baker, M.I.C.E., the strongest gusts gave a momentary pressure of 35½lb. per square foot on the large board, 300 square feet area, and not less than 65lb. per square foot on the small board, containing 1·5 square feet.

On Monday last, Dr. T. Hudson delivered a lecture on "Rotifera" to the Midland Institute, Birmingham, in the course of which he stated that one very remarkable thing about them was that under certain conditions they could be dried and kept for three or four years, and could be brought to life again by moisture. The world of the Rotifera, said Dr. Hudson, is full of marvels, and they can be seen with microscopes of small power.

The Birmingham School Board propose to establish technical schools at a fee of 3d. per week. The course of study will run over two years, and will be taken up by those desirous of becoming skilled artisans who have passed the sixth standard. The curriculum will consist of elementary instruction in those sciences and arts upon which the trades and manufactures of Birmingham are based, and of practical training in the use of ordinary workshop tools.

In Liverpool, the "Acme" system of electric lighting is being tried. It consists of a primary battery, costing £50, which will give 20 lights of 20 candle-power during 46 hours. It is added that the cost of maintenance is "perhaps a little more than the price of gas."

According to Prof. Wanklyn, the manufacture of gas from limed coal (Cooper's patent) is a success, as it reduces the amount of sulphur compounds to three grains in the 100 cubic feet, and increases the yield of ammonia and tar by the abolition of the lime purifiers.

The Midland Railway Company has decided (upon the report of Mr. A. A. Langley) to key the rails *outside* instead of *inside*, as at present, the great reason for the change being the very large number of chairs annually broken. The company's locomotive committee has decided to paint the engines and tenders brown (the same colour as the carriages) instead of green; and it is under consideration to also paint the Pullman cars a similar colour: but upon this point the carriage and waggon committee has not yet finally settled.

According to the Patents Act of last year each applicant is required to make a declaration under an Act passed in 1835, and in the various articles upon the former Act which have from time to time appeared in the press, it has been stated that this declaration must be made before a magistrate. It appears, however, that notaries are empowered to take the declarations made under the Act of 1835. Mr. Wm. John Grey, Notary Public of Newcastle-upon-Tyne, communicated with the Board of Trade on the subject, and has received a letter stating that the declarations may be made either before a magistrate or a notary.

USEFUL AND SCIENTIFIC NOTES.

Natural Barometer.—The natives of the Chiloe Islands make use of a curious natural barometer, to which, from its having been first noticed by the captain of an Italian corvette, the name "Barometro Araucano" has been given. This novel weather guide was described at a recent meeting of the Linnean Society of New South Wales, as the shell of a crab, one of the *Anomura*, probably of the genus *Lithodes*. It is peculiarly sensitive to atmospheric changes, is nearly white in dry weather, but exhibits small red spots on the approach of moisture, and becomes completely red in the rainy season.

Gold Ink.—For making gold ink the following has been quoted in the *Chemist and Druggist*:—Take equal parts of iodide of potassium and acetate of lead; put them on a filter, and pour over them twenty times the quantity of warm distilled water. As the filtrate cools iodide of lead separates in golden scales. This is collected when the filtrate has quite cooled, washed with cold water on a filter, and rubbed up for an ink with a little mucilage. The ink thus made must be shaken every time it is used.

M. Chevreul.—After a service of more than half a century as director of the Gobelins Manufactory, this illustrious chemist has been placed on the retired list, and although in less than two years he will have completed 100 years of age, he considers that he has not been well treated. It would appear, however, that in order to spare the feelings of the old gentleman, he has been allowed to retain his appointment with the full salary attached to it. The Municipal Council of Paris has given his name to a new street in this city—an honour rarely conferred on persons while yet living. The following short account of his habits may be of some interest. He is generally lightly clad, and wears no hat unless under circumstances in which he is obliged to appear in one; indeed, he hardly needs a hat, as he has most luxuriant hair. He is constantly at work, allowing only ten minutes for each of his meals, of which he has but two a day. He breakfasts at seven, the repast consisting of a plate of meat and another of vegetables, which he eats together, the whole being washed down with two tumblers of water. He is said to have never drunk a glass of wine in his life. He dines at seven in the evening, and takes nothing between the two meals except a small loaf at noon, which he eats standing and by the side of his alembics. The writer who relates this states that on a visit to M. Chevreul he found him in the attitude just described, and on expressing his surprise at the frugal manner in which he lived, M. Chevreul observed: "I am very old (this was in 1871), and I have yet a great deal to do, so I do not wish to lose my time in eating." This example of longevity is certainly a good argument in favour of temperance and regularity of living.—*Lancet.*

LETTERS TO THE EDITOR.

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

MAGNITUDES OF STARS IN CASSIOPEIA, γ VIRGINIS, &c.—ASTRONOMICAL DIAGRAMS — SELENOGRAPHICAL — STANDARD STARS — ASTRONOMICAL WORK.

[22312.]—Some time since there was some discussion in the columns of the "E. M.," concerning the possibility of variability in β and ϵ Cassiopeiæ. I now forward a selelection from my observations of γ, β, δ, and ϵ Cassiopiæ. I have only included the most trustworthy.

Mon.	Day.	β	γ	δ	ϵ	Standard.

I am not so sure about the observation of β upon January 2, 1883, as about the other observations. With this possible exception, the observations give no ground for the assumption of variability in β. As to ϵ, I think the variation shown is too great to be explained by the assumption of error. I would draw attention to the observations of δ. I have a strong suspicion that this star is variable to the extent of ·3 or ·4. Neither do the above observations reveal any variability in γ. If γ Cassiopeiæ be variable at all, it must, I think, be extremely irregular.

I must thank "H. S." for the information which, in letter 22120, he so kindly gives me. Concerning what he says about my comments, upon his saying that faint coarse pairs are not worth cataloguing—I may remark, that if these objects are not entered in catalogues of some kind, it is difficult to see how readily accessible and practically useful knowledge of them is to be preserved. I hope that some of those observers who pay attention to the variability of stars will remember to watch β 607 and Arg. (− 0°) 2600 occasionally.

The remarks which have been made in "ours" recently concerning the reproduction of astronomical sketches, suggests the inquiry whether no one among the numerous readers of the "E. M." will contribute to its pages an account of the best way of drawing and preparing such sketches for the engravers. I am sure that plenty of the readers of "ours" would be very much indebted.

In letter 22073 (p. 280) "M. A." takes notice of my remarks upon selenographical work in letter 22036 (page 239). Concerning his comments, I may say one thing—that while it is possible that I may have "a mistaken idea of selenographical work," it is certain that he has a mistaken idea of my meaning. I am not so foolish as to imagine, as "M. A." imagines I do, that "it is necessary to possess all the works of the great Selenographers in order to do useful lunar work." My objection to the introduction of much technicality into selenography, is not that it renders it difficult to "grasp easily," but that it is the tendency of technicality to render science hard, dry, and uninviting, just as it is the tendency of specialism to hinder the attaining of a just and broad view, and to render the specialist apt to put an undue value upon details. But technicalities and specialism, alike, are almost certain to have one result—a result destructive of the interest felt by the amateur—they are almost certain to destroy imaginative pleasure. How "M.A." can say that I "certainly have a mistaken idea of the use of the District Catalogues" when I made no mention of my ideas upon the subject, puzzles me. I said that they are "unsatisfactory substitutes" for Mr. Birt's papers—and so they are. But that does not affect the fact that they are of great value, for *their specific purpose*. But the mere fact that they are dry lists of objects, position angles, and relative distances, put together for one definite end, deprives them of all power to stimulate the imagination—whether to the better realisation of existing knowledge, or to the conception of other ways of acquiring new. I could have wished that "M. A." had stated his own "idea of selenographical work." The "lunar work," which, he says, the District Catalogues "will be found to simplify," can only be work in *one* of the various branches into which selenographical and selenological work will be found to divide. The confirmation or disproof of the existence of objects already registered and the discovery of new ones, are not the only pieces of work which may be undertaken. It is a pity that no one now contributes to the "E. M." notes as to what definite information is wanted concerning definite objects. Will Mr. Elger contribute notes of this kind? They would differ from his extremely valuable "Selenographical Notes" in the *Astronomical Register*, in not being so much records and discussions of work done, as hints and guides as to work which should be done.

Perhaps the most important at present among the various objects of lunar study are the *Light Rays, Spots, and Streaks*. It may, perhaps, be well if I here quote a passage from a letter written by Mr. A. Stanley Williams to the *Astronomical Register* in December, 1882. That excellent observer (concerning whom I may say that many must regret, as I do, his almost complete disappearance from these pages) expressed himself thus:—"It is a singular circumstance that the lunar light-streaks, which form one of the most extensive classes of objects visible on the moon's surface, have, up to the present time, nearly entirely escaped attention. Observers have spent the greater part of their lives in recording the numerous craters and mountains visible on the lunar surface, but have scarcely bestowed more than a passing glance upon this important class of objects. It is more unaccountable because their features are probably better suited than any other to reveal *real* changes which may take place, and are also particularly well suited to afford evidence of the presence of an atmosphere. There are but very few formations which have been studied sufficiently well to give even the more prominent light markings, whilst those which have been subjected to what may be considered a fairly exhaustive examination, amount to only three or four. In all the last-mentioned cases, it may be remarked, considerable changes have been seen to take place, due, perhaps, in great measure to the presence of a lunar atmosphere, and it is certain that an observer who diligently studies these features, even with an instrument not exceeding two inches in aperture, may expect an abundant harvest of valuable results." So far as my limited experience in the observation of these objects goes, it fully bears out the truth of Mr. Williams' remarks. I have principally observed the ray-system of Proclus. Concerning this system, I would make one remark—either the difficulty of seeing the rays has been overrated, or they have increased in brightness. Mr. Webb says (following, I suppose, Beer and Mädler) "It is the centre of several bright streaks, not very easily seen." And in a back volume of the "E.M.," "F.R.A.S.," in giving *lunar tests* for a 3¼in. refractor, says, "He may also try, under suitable illuminations, to make out the system of light-streaks round Proclus." My experience has been different. Not only do I find the principal rays *easy* with my 3¼; but I see them from shortly after sunrise to shortly before sunset. I see a good deal of the detail also, and have little doubt that, with favourable weather, I may be able to complete a map of the system. I have been using Dennet's map (given in the "E. M." for September 5, 1879) for reference. I have confirmed the existence of most of his rays; but attribute them, in several instances, to other centres of origin. As far as I can make out, Dennet's ray IX. issues, not—as he makes it do—from the same centre as his I., but from the same centre as his VIII. In regard to Dennet's IX. (indeed, I think in regard to some more of the rays) I have made a curious observation, and one which bears upon what Mr. Williams, in the above extract, says concerning the possibility of detecting signs of obscurations by means of observation upon the rays, IX. ends a little to S.E. of Cleomedes F. Just within the E. border of the Mare there is a *white spot* upon the ray. Between Cleomedes F. and this white spot the ray seems always to be of the same degree of brightness and distinctness; but between the white spot and the origin, the ray is at some times much fainter than at others. The rays seem to me to be of different classes; some being narrow and definite, and others diffuse and cloud-like. I have sometimes wondered why Mr. Birt's excellent classification of the Rays into Tychonic, Copernican, and such as might be similar to the "comet-tail" of Messier, has not been generally adopted.

In regard to what "M. A." says about my sketches in letter 22036, p. 239, I may say that, in in that of Plato, it is quite possible that the object I conjectured might be Schröter's χ may be placed a little too far east. As to his remark that "the ridges B in his sketch, between Picard and Pierce, may be the same as that mentioned in 'Lunar Work' in the *Astro. Register* for Feb., 1883," I would like to know *which* of the ridges there mentioned he means? So far as I can make out, all the observations by Miss Ashley reported there have reference, with one exception, to the different portions of Schröter's forked ridge. But my ridges B can hardly form any part of that object, for they lie either *between* Picard and Pierce, or *east* of the line joining them. It is stated (*loc. cit.*) that on Aug. 1, 1882, at 14h., Miss Ashley saw a low ridge connecting Picard and Pierce. (Aperture and power are not stated.) This observation might bear upon the identification of my western ridge B, but cannot upon the eastern. But I did not see anything like a connection between the extremities of the western ridge with the walls of either ring-plain.

I must now answer "Stella," who put to me upon p. 351 a query (52516) concerning "Standard Stars," and before replying, allow me to request "Stella," not to consider me dilatory and discourteous. The usual way of selecting magnitudes for standard stars seems to be to take the magnitude given by Heis, and express it decimally. I do not specially admire this plan, principally for the reason that it is putting a definite value upon what is avowedly *indefinite*; but if standards are to be taken from Heis they are better to be selected from among those stars, his estimates of which are identical with those of Argelander. For myself, I prefer following the "vulgar" magnitudes in Sir John Herschel's table of "Vulgar" and "Photometric" magnitudes. Here are some from Heis and Argelander:—1·0, Aldebaran, Spica, Rigel; 1·3, Regulus, Altair; 1·7, α Cygni, Castor; 2·0, β Tauri, β Ceti, β Leonis; 2·3, γ Urs. Maj., β Herc.; 2·7, η Canis, κ Orion, ε Cygni; 3·0, ζ Leonis, θ Urs. Maj., β Can. Min.; 3·3, ζ Tauri, ν Urs. Maj., λ Orionis; 3·7, ο Leonis, β Cancri, η Aurigæ; 4·0, ν Persei, π And., τ Orionis; 4·3, δ Urs. Min., 10 Tauri, γ Trianguli; 4·7, χ^1 Orionis, κ Aurigæ, 88 Tauri; 5·0, ρ Orionis, 26 Urs. maj., λ Arietis; 5·3, 97 Tauri, η Arietis, φ Aurigæ; 5·7, μ Aurigæ, 93 Tauri, π Arietis; 6·0, χ^3 Orionis, 68 Virginis, 114 Tauri. As to my own observation, Procyon is the only star which I feel pretty sure is exactly 1·0. Sir John Herschel gives Vega and Capella as being also 1·0; but I rather think they are one or two tenths brighter. They are, however, difficult to compare. I know of no star *exactly* 1·5; but I find Pollux 1·4. Flammarion makes Altair 1·5. I find α Andromedæ, γ Orionis, and α Ophiuchi constant at 2·0. α Persei I estimate at 2·1, and Polaris at 2·2; and I find these stars the best of all standards. I make β Aurigæ and α Arietis, 2·3; and β And. 2·4, and γ And. 2·7; but I know no star exactly 2·5. 3·0, η Draconis, α Cephei, and β Arietis. 3·1, β Draconis and γ Urs. Min.; 3·2, η Boötis; 3·3, δ Draconis, and α Can. Ven.; 3·4, γ Lyræ (this star is entered in Messrs. Espin, Gage, and Read's Catalogue, but I altogether doubt it being variable); 3·5, α Draconis, λ Tauri, γ Ceti; 4·0, ν Cygni, ζ Cephei, λ Boötis; 4·2, κ Cass.; 4·3, κ Cephei; 4·5, 5 Tauri, 35 Arietis; 5·0, φ and 50 Boötis, σ and 50 Draconis. I hope that these lists will help "Stella," and will be willing to help him further if I can.

I was very glad to see the letter on p. 301, signed "Orion," on "Specialism in Astronomy." I only differ from the writer in thinking that astronomy is not only "one of the," but *the* "most interesting and attractive of the sciences." How many agree with us both, your invaluable pages, Sir, amply attest. But large as is the amount of work done, much more *might* be done. "Orion" speaks of "'common' work, which may be done with the naked eye, or with optical means at the command of almost anyone." This is literally true. Much may be done, even if the observer have nothing else to work with but his unassisted vision; and much more may be done if he have an opera-glass to help him. I have paid a good deal of attention to the matter, and speak from personal experience. But this "common" work stands in need of classification. In a private letter, "Orion" remarks, "it should be remembered that many, who study astronomy for pleasure, would be glad to do a little work on subjects which lie, as I may say, at hand, but would have a most decided objection to go into recondite details. But," he continues, with perfect truth, "if these subjects are not brought before their eyes, they are not likely to trouble themselves in the matter."

Will Prebendary Webb, Mr. Franks, "F.R.A.S.," Mr. Espin, and Mr. Denning give their aid and encouragement? More especially would I like from Prebendary Webb and Mr. Franks some advice on the observations of star-colours, and particularly with regard to the degree of success with which they can be conducted with naked eye and opera-glass. Another remark I would make is this: it is commonly overlooked that a good deal of elementary astronomy can be properly learned, and a good deal more properly comprehended and realised, by naked-eye study alone.

S. Maitland Baird Gemmill.

Glasgow.

PONS-BROOKS.

[22313.]—I notice the inquiry in regard to the brightness of comet Pons-Brooks in letter 22218, p. 408. I beg to say that I have been trying to compare its brightness with the stars upon Heis' New Atlas, ever since it became certainly visible to my unaided eye on Dec. 15th. On that date and on the 16th, I strongly suspected it was the comet; but on the 17th I became positive of it, and could pick it up with the naked eye before setting the telescope.

My comparisons commence on the 17th, at which time its brightness was estimated as fully equal to either of the two stars b^2 and b^3 Cygni, and somewhat brighter than one of them, and I believe that, with perhaps one or two exceptions, the observations were carried on upon every clear night since that date. At first, when it appeared merely like a faint star, there was not much difficulty in comparing it with neighbouring stars; but when it began to assume a hazy and cometary look, I experienced some trouble in trying to assign its approximate brightness. It would catch my eye perhaps as soon as some definite star; but when I came to compare them critically, the intrinsic brightness of the star was so much in excess that it was difficult for me to satisfy myself. Still, by looking up suddenly and noting what objects caught my eye at same time, then noting which was the comet and comparing it sideways with the star and then running my eye rapidly from one to the other, —by keeping this up for some time I think I got about as near to it as it was possible for a fellow who was trying the matter for the first time.

The following are selected from my observing-book:—

Jan. 9th.—Just about equal to Zeta Pegasi; sometimes with averted vision suspect it as slightly brighter. Slightly brighter than Mu, but decidedly not as bright as Eta Peg., and Epsilon Peg. still much brighter than comet. Suspect at times a faint trace of tail not more than ¼°, but it always vanishes with steady gazing. A spell of cloudy weather then set in, and comet could not be seen until—

Jan. 13.—Almost equal to Alpha Peg., sometimes suspected as fully equal to it; certainly somewhat brighter than Gamma Peg., but not as bright as Alpha Androm. (There is something wrong here in my estimate, as Heis has both of these stars as 2nd mag.; but that is the way it went down in my note-book before referring to the Catalogue.) Looks like a star with only a small trace of nebulosity. Can't say that I see any tail, except at times a faint trace by averted vision, but short at that. Disappointed about tail, but nucleus is much brighter than when last seen, and much brighter than expected by me. (The moon was up, but behind a heavy bank of clouds in the east, and did not come out for five minutes or more.)

Another spell then set in, and comet could not be seen until

Jan. 17th.—Tail much easier seen than expected. Pretty plain for 3° or 4° or so, and think that when seen sideways several degrees longer—possibly 6° or 7° total. Hard to estimate this, as unused to such distances. (When I came down I marked position of comet on the atlas, and by comparing its distance from the stars Beta and Eta Ceti, found that its suspected length was well on to 10° or so. It was only bright and evident for 3° or so, and balance was faint and seen only sideways. Still, I think it was faintly visible at times to that length.) Nucleus pretty plain, not as bright as Beta Ceti, but nearly equal to Gamma Peg., brighter than Eta or Theta Ceti. Tail seems pretty straight, and spreads (afterwards, through the telescope, the tail I thought appeared slightly curved). Nucleus and head did not strike me as being as bright as on 13th.

The above are all naked-eye observations. It will be seen that at the very time its calculated brightness was greatest, it was invisible here; but I suppose plenty of your readers saw it at that time. I should judge that when at its brightest, it was fully equal to a 2nd mag. star. Did it not therefore exceed its calculated brightness somewhat?

I would also like to ask whether any of your observers noticed anything peculiar in the appearance of the comet's nucleus and head on the night of Jan. 13th – that is through the telescope.? I was observing it with my 4in. equatorial by Cooke, of York, and with a comet eyepiece, p. 25, at about 7h. 30m., 75th meridian time. The following abstract is from my observing book:—

A strange change in nucleus or coma. Never saw it look this way before. A *sharp* and *distinct* stellar point, surrounded by a bright almost circular nebulosity, and then outside of this the regular faint coma. The stellar point small, and brighter than the circular nebulosity, and perfectly distinct from it. The circular nebulosity somewhat fainter, but perfectly distinct from the coma, and the coma faint and indefinite; three grades as it were. I estimate the *diameter* of the bright circular nebulosity as about 1', by a rough comparison with the companion of Delta Orionis.

On the 17th, when next seen, nothing like the bright circle could be seen. Nucleus was strongly condensed, but the sharp and distinct stellar point in centre was not visible, nor have I ever seen anything like the same appearance since.

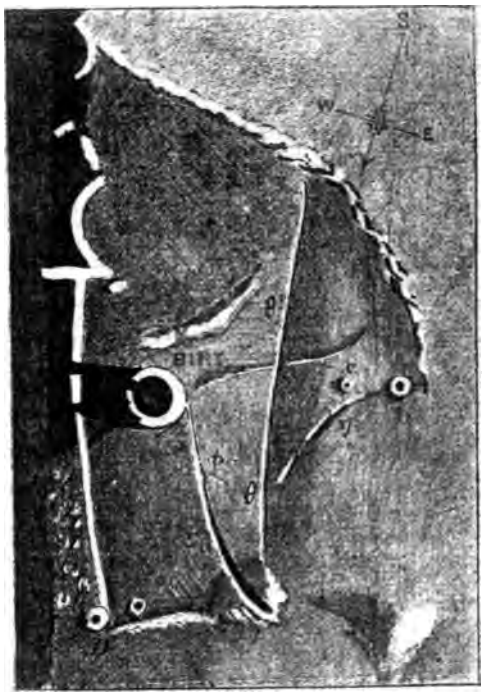
At the risk of being "sat down upon," and placed in the category of those gifted with vision bordering on the miraculous, I send you this account of appearance of comet on the night of Jan. 13th. It seemed to me like a strange change, and was so sharp and obvious that it caught my notice as soon as I looked into the eyepiece. At 7h. 20m. the moon was out of the clouds in the east, and with comet eyepiece "the tail could be seen about 1¼° pretty plain, and perhaps 1½°, but after that uncertain."

In regard to the naked-eye estimates above, I used only the Atlas of Heis in identifying comparison stars, and after making notes and coming down from Observatory, referred to his Catalogue, where the magnitudes were subdivided closer. Sometimes I found my estimates agreeing very well with him, and sometimes I found myself "off," as, for instance, for some cause or other, Tau Cygni always seemed somewhat brighter to me than Nu, although both are 4th mag. in the Catalogue. **W. H. Hennesay.**

Baltimore, U.S.A., Jan. 22.

SELENOGRAPHICAL—BIRT—MESSALA

[22314.]—"M. A.," in his interesting communication (22238), relating to clefts observed by him on 24th November, 1880, in the neighbourhood of Birt, describes and draws a long straight cleft extending in a southerly direction from a conspicuous hill on the north of Birt to the range of ridges on the east and south of it, and refers to an observation of my own which, as the inclosed sketch will show, was made under a very similar angle of evening illumination. The date of my drawing is 23rd October, 1883, 17h. to 18h. 10m. On that occasion two clefts were visible, one marked ϕ, and the other θ. The former was traced from the foot of the eastern wall of Birt to the hill (1) into which it cuts, as shown. The latter (θ) appears to originate at the same hill, and runs in a southerly direction at the bottom of a shallow valley till it encounters the *ridges on the south*-east of Birt, beyond which it was *not seen. I think there* can be no doubt that the cleft marked ϕ in my drawing is the prominent cleft shown by Schmidt and Neison almost precisely as I have drawn it—the southern continuation of which (ζ) is so rarely seen. If this be so, the cleft shown by "M. A.," passing some distance to the east of Birt, and terminating at the above-mentioned ridges, must be that marked θ in my sketch, and not ζ, as "M. A." supposes. I have many drawings showing the cleft ϕ, which is always seen terminating apparently close under the foot of the east wall of Birt, and I invariably find it a far easier feature than θ. On the same day, 23rd Oct., 1883, I noted a very delicate cleft (η) extending from θ towards craterlet *b*.



Messala.—With respect to the semicircular ridge observed by "M. A." outside the east wall of Messala, corresponding to a similar object in the interior of this formation, I may say that a drawing made at 11h. on 18th September, 1883, shows this feature very distinctly, and from "M. A.'s" description doubtless agrees very well with his own observation. **Thos. Gwyn Elger.**

Kempston, Beds, 29th January, 1884.

GLASS DISCS FOR REFLECTORS.

[22315.]—In answer to "Caplatzi" (22308), I most willingly give the result of my experiments on the safe thickness of glass specula, and it just amounts to this, that to be perfectly free from danger from flexure with the ordinary usage of the amateur, the speculum ought to be no more in diameter than six times its thickness; and even then, I should not say carelessness in the mode of support on the machine while polishing and figuring, or carelessness in mounting in the telescope, would go unpunished, though I believe it is possible to make a speculum free from flexure, whose diameter is twelve times its thickness, for I have done so myself, and I think there is no difficulty in it to one who is aware where the important points lie to be attended to. These, I think, I have pretty well ventilated in my letters on the grinding and polishing of glass specula, and, perhaps, now that the attention of amateurs is called to the importance of avoiding flexure, they will be more careful in the future; in which case I should say it would be safe to cut "Caplatzi's" glass into discs up to nine times their thickness. It is well for all to remember into what ratio the strength increases with the thickness. It is the square of the thickness that gives the ratio; thus a speculum twice the thickness of another is four times its strength in resisting flexure, and a speculum in diameter nine times its own thickness, would be about double the strength of another in diameter twelve times its own thickness.

The best way I know of getting the glass cut up into discs is to get it cut up into squares the size, or a little larger, say ¼in., than the discs I require. This would be done at the shops or works where they sell such glass. I should then take these squares to glassworks where glass cutting is carried on (and I believe there are several in London), I should get the corners cut or nipped off, and the whole rounded on the glasscutter's wheel; this they can do very nicely if they like, and the disc will then require no grinding of its edges by the amateur. This will save a lot of trouble; and further, while at the glasscutter's shop, the surface (the rougher one) had better be hollowed out to a gauge of the curve, the radius of which is about eighteen times the diameter of the disc; the amateur will then be able to make it what focus he likes, the rough work having been done for him. This will save him a lot of trouble, if the glasscutters are careful, for they cut the glass away on a wheel with sand, and not on a tool like the amateur; and, therefore, the importance of a gauge that tests two diameters at once at right angles to each other. This gauge I have drawn and described in Vol. XXXIII. p. 621. This mode of procedure I find the readiest, since I live within a short distance from glasshouses and glasscutters. **H. A. Wassell.**

Addenbrook Villa, Love-lane, Stourbridge.

[22316.]—I should not advise Mr. Caplatzi to cut his squares of glass (1¼in. thick) into discs larger than 8½in. diameter. I think he is wrong respecting the rigidity of cast and rolled or plate glass. I have tested the two by equal uneven supports of the mirrors, and found *less flexure* in the cast ones. The crystallisation, *if I may so term* it, of the cast glass is not disturbed by the *rolling*, which is necessary in making plate. Something analogous might be said of a cast-iron plate and a rolled one: though the material is not exactly the same, the cast one would certainly be the most rigid.

My 12½in. discs (cast) are 1⅝in. thick, and require a fortnight annealing. I should think he might safely cut his glass up into 5½in., 6½in., and 8½in. discs, and employ the rotating ring, as the diamond, hammer, and pincers process is only a risky one, and the edges would require grinding.

W. S. Scott, Southwick, Sunderland.

PARAFFIN LAMPS AND BURNERS.

[22317.]—Having had a good deal of experience in the use of paraffin lamps, I can inform "Os" (letter 22282) that old paraffin burners are as good as new ones.

Put them in strong soda-water, or dip them in aquafortis. The small perforations are stopped with dirt. If the wick does not wind up, wrap a piece of emery cloth round a narrow piece of hoop iron and clean the wick tube, and always well air the wicks just previous to putting them into use.

C. B.

[22318.]—'Os's" oilman is in error. I possess one of Hincks's "Duplex," have had it burning nearly every night for twelve years, and there is nothing the matter with it yet. It *is* the wick which is in fault. In time the wick becomes clogged, in the manner of a filtering *paper*, and the oil cannot ascend in a proper manner. *There*fore, place clean wick, that which fills the burner to the $\frac{1}{16}$th of an inch; the oil will swell the wick to the full size of burner. Also clean the carbon deposit from inside the top of burner with a penknife. All will go right then, and the thin violet flame will disappear. **Cymru.**

TRICYCLES.

[22319.]—In your issue of the 13th, I read a letter from "Rug" (letter 22251) asking for information about certain points with regard to tricycles. In 1882, I had the use of a first-class machine, cranks-and-chain class, and, like "Rug," got on very well on the level, but found it very hard, slogging work when I came to any rise in the road. Early last year, after many inquiries and trials, I decided on the Omnicycle; and now, after 12 months' use and running over more than a thousand miles, I have formed a very decided opinion on the subject. I believe the principles on which it is built are in the right direction. Its chief points of merit are: No dead points; very easily altered from speed to power for hill-climbing; the feet remaining on the treadles at rest while running down hill. I think there are other machines built on this principle, though I have not seen anything like the Omnicycle. "Rug" would never find himself under the necessity to dismount, or turn the wheels with his hands, to get over a dead point on a machine of this class; for whether you make a long stroke or a short one, the machine must go on, and when one foot has finished a stroke it is taken up on the instant by the other. This is effected by a ratchet and click arrangement on the main shaft. Some have objected to this machine, because it will not go backwards when in gear, but I find it a positive advantage, for when going up-hill I can stop to look about me without using the brake. And some object to its seeming complicated mechanism that it would soon show signs of wear; but after 12 months' almost constant use it appears to me as perfect as when I first had it.

"Rug" seems to think that a coiled spring might assist in climbing hills. I think a coiled spring of sufficient strength to be of any use would add very materially to the weight of the machine, and it would be a constant weight. In your issue of

December 14th (22133), J. A. Ollard inquires what speed can be got out of the Omnicycle. In August last year, returning home after a 20 miles' spin, I came on a nice level bit of road, and with the wind on my back I thought I would try the *measured mile*, and took accurate time by my watch. I did the mile in 4 minutes 30 seconds. Another time, under same condition, but another road, five minutes, but had to stop half-way because of two carts in the way. A third time, a stiff breeze behind me, four minutes. I don't mean to say that I could do 15 miles in an hour, for I do not think it wise for anyone past middle age to run such a distance against time. I dare say a younger man might get more speed out of it; but I think eight miles an hour is quite fast enough for ordinary travelling.

Nedof.

ELECTRO-MAGNETS.

[22320.]—It seems to me that "X. N. X." (letter 22306) has made the mistake. He should have tried the experiment with the keeper on, and again with it off, not hung his weight on the keeper.

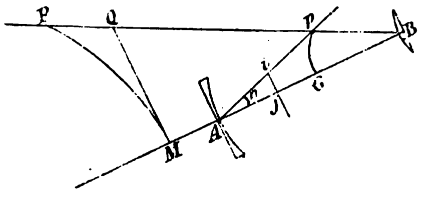
T. B.

THEORY OF THE EYEPIECE.—IV.—DISTORTION OF CURVATURE.

[22321.]—Hitherto we have only been concerned with the aberrations of a particular ray of light falling eccentrically upon one or more lenses. Now, however, we enter upon quite a different part of the subject—namely, the *form of the image* And here, it may be observed, we are concerned with three images, which we may call the first, the second, and the final. The first being that which is formed by the o.g., the second that which results from the refraction of the rays by the field lens, and the final that which results from the refraction by both lenses together.

This last differs from the first image, not only in magnitude, but also very considerably in form; and, in fact, as I shall try to show, the difference of form, &c., thus arising seems to be by far the most important element in the theory of the eyepiece, although it appears to have received much less attention than the aberrations; a fact which, perhaps, may be explained by the circumstance that in the case of an o.g. the difference in form between the image and the object is of no importance whatever compared with the aberrations, and is, moreover, irremediable; whereas in an eyepiece, on the other hand, it appears to admit of correction to quite as great an extent as the aberrations do.

We may now define the distortion to be "the distance between any point of the final image from the place which it would occupy if this latter image were similar to the original one." Thus, suppose that the first image were a straight line, and the latter a curve, MP, as in the figure, the distortion of the point P will be represented by QP; or since QBM is always small, it may be represented approximately by BQ÷BM. This is a quantity which can be easily found, and may be called approximately the distortion, remembering always that, if necessary, a correction may be applied for greater exactness.



Let us first find the distortion of a single lens placed at A. Let I i be the original image, G r the second image. A I = b, A G = c, I A i = θ. Then by the definition given above, the approximate distortion will be Ap − c. Now, by formulæ for lenses,

$$\frac{1}{\mathrm{A}p} - \frac{1}{\mathrm{A}i} = \frac{1}{f} = \frac{1}{c} - \frac{1}{v}$$

or—

$$\frac{1}{c} - \frac{1}{\mathrm{A}p} = \frac{1}{b} - \frac{1}{\mathrm{A}c} = \frac{1}{b}\,(1 - \cos.\,\theta)$$

$$\therefore \text{ distortion } = \mathrm{A}p - c$$

$$= \frac{c^2}{b}\,(1 - \cos.\,\theta) \text{ nearly } \ldots. \quad (a)$$

or if h be the height of the image from axis,

$$1 - \cos.\,\theta = \tfrac{1}{2}\,\frac{h^2}{b^2} \text{ nearly,}$$

or distn. $= \frac{1}{2}\,\frac{c^2 h^2}{b^3}$ or when the lens is used as an eyepiece, c becomes nearly the distance of distinct vision, and b becomes f nearly,

$$\text{or distn.} = \tfrac{1}{2}\,\frac{c^2 h^2}{f^3} \ \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (b)$$

We may now find the distortion of a pair. Let a second lens be placed at B. Through p, the extremity of the second image, draw the secondary axis BpQP. Let P be the conjugate focus of p, and M that of G. Then,

$$\frac{1}{\mathrm{BP}} - \frac{1}{\mathrm{B}p} = \frac{1}{f_2} = \frac{1}{\mathrm{BM}} - \frac{1}{\mathrm{BG}}$$

$$\therefore \frac{1}{\mathrm{BM}} - \frac{1}{\mathrm{BP}} = \frac{1}{\mathrm{BG}} - \frac{1}{\mathrm{B}r}$$

Or, distortion = BP − BM = $\frac{\mathrm{BM}^2}{\mathrm{BG}^2}(\mathrm{B}p - \mathrm{BG})$ nearly. Now by trigonometry, if AB = d, and θ be small Bp = $d - \mathrm{A}p + \frac{d\,.\,\mathrm{A}p}{d - \mathrm{A}p}\,(1 - \cos.\,\theta)$ and BG = $d - c$, or

$$\text{distn.} = \frac{\mathrm{BM}^2}{\mathrm{BG}^2}\left(c - \mathrm{A}p + \frac{dc}{d - c}\,\overline{1 - \cos.\,\theta}\right) \text{ nearly}$$

$$= -\,\frac{\mathrm{BM}^2}{\mathrm{BG}^4}\left(\frac{c^2}{b} - \frac{dc}{d - c}\right)(1 - \cos.\,\theta)$$

by what has gone before.

Now $\frac{c}{b} = 1 - \frac{c}{f_1}$, therefore the above is easily reduced to distn. $= \frac{\mathrm{BM}^2\,c^2}{f_1\,\mathrm{BG}^3}(f_1 + d - c)\,(1 - \cos.\,\theta)$.

This will be the distortion for any pair of lenses; but for an eyepiece it takes rather a simpler form, for BG or $d - c$ becomes f_2, and BM the distance of distinct vision nearly = v suppose, and it becomes

$$\text{distortion} = \frac{b^2\,(d - f_2)^2}{f_1 \quad f_2^3}\,(f_1 + f_2)\,(1 - \cos.\,\theta)$$

$$= \tfrac{1}{2}\,v^2\ h^2\,\frac{(d - f_2)^2}{b^2}\,\frac{f_1 + f_2}{f_1\ f_2^3} \text{ as above,}$$

$$\text{or since } b = \frac{f\,(d - f_2)}{f_1 + f_2 - d} \text{ we have finally}$$

$$\text{Distortion} = \tfrac{1}{2}\,\frac{v^2\,h^2}{f_1^3\ f_2^3}\,(f_1 + f_2 - d)^2\,(f_1 + f_2) \ldots \text{A.}$$

This is the value here proposed for the distortion of a point in the image whose distance from the axis is h; and we see first that it varies as the square of h; next, that it is the same in whatever order the lenses are placed; and thirdly, that when f_1 and f_2 are both positive, the separation of the lenses diminishes the distortion.

It will now better be seen what a great nuisance distortion is, for not only is the form of the final image very different, in consequence of it, from that of the original; but also if the right side of (A) is very considerable, as it generally is, the points in the final image will be at such different distances from the eye that they cannot all be in good focus for distinct vision at the same time; hence there will arise *indistinctness*; and lastly, as the blue and red rays are unequally distorted, and considerably so, owing to the high powers of f_1, &c., and the distortion varying as h^2, the colouring will increase rapidly as we approach the edge of the field; and, indeed, it may not be too much to say that it is owing to this cause that colouring is visible at all. Thus, when we use a single lens, which, of course, is not achromatic, we do not perceive colouring near the centre of the field, though, of course, it must exist, but not in sufficient quantity to make a distinct impression of colour upon the eye, yet enough to impair the definition.

In the case of an o.g., however, the difference of colouring between the central and peripheral portions of the field is very much less striking, and perhaps would be quite imperceptible but for the colouring introduced by the e.p.

To return now to our equation, and put it into a form adapted to comparison with the distortion of the equivalent single lens: The distortion of the latter we have seen to be $\mathrm{D}^1 = \frac{1}{2}\,\frac{v^2\,h^2}{\mathrm{F}^3}$ v being the same in both, since it must be in each case the distance of distinct vision nearly; also $\frac{1}{\mathrm{P}^3} = \left(\frac{f_1 + f_2 - d}{f_1 f_2}\right)^3$ by means of which we easily obtain the very simple form

$$\frac{\mathrm{D}}{\mathrm{D}^1} = \frac{f_1 + f_2}{f_1 + f_2 - d} \ \ldots\ldots\ldots\ldots\ldots\ldots \ (\mathrm{B})$$

In a Ramsden this ratio becomes 3 : 2, and in a Huyghenian 2 : 1; whence the distortion of the first is to that of the other as 3 : 4. And this explains why it is that it gives a flatter field.

From this, as well as from results given in previous papers, it would seem that all the three objectionable quantities—dispersion, distortion, and sp. ab. are much greater in a Huyghenian than in the equivalent single lens, the two first being twice as great; so that a Huyghenian would seem to be a most sorry substitute for a single lens, if we made $2d$ strictly $= f_1 + f_2$.

The answer which will very likely be given by some, is simply this: "Pooh-pooh—absurd; if you will unscrew the field lens and use the other only, you will find the field is very much worse, especially towards the edges, and the colouring much greater, as it ought to be, when we substitute a single lens for an achromatic pair."

To this I would rejoin, that the objector is using quite a different standard of comparison. It is one thing to compare it with the *equivalent* lens, and another with the eye-lens. We have already compared it with the former; let us now with the latter. In form. (A) put $f_1 = 3f_2$ and $d = 2f_2$, it becomes $\mathrm{D} = \frac{1}{2}\,\frac{v^2 f^2}{f_2^3}\,\frac{16}{27}$; but distortion of eye-lens alone $= \frac{1}{2}\,\frac{v^2\,h^2}{f_2^3}$, the ratio of which is 16 : 27, and the increase of distortion producing an increase of colouring, the explanation is evident why the field produced by one lens alone is much worse than by the pair.

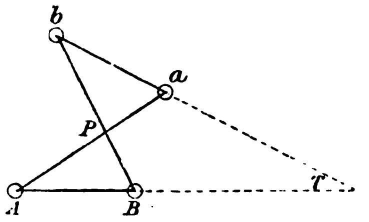
That the difference in colouring is due to the effect which the distortion has upon it, and not to the eyepiece being achromatic, is evident, as follows: when we give a further separation to the lenses, we diminish the colouring, as Mr. Bradbury somewhere says; but we also by so doing should destroy the "achromatism"—at least, if what is popularly thought about it were true, so that, by destroying the achromatism of the eyepiece we should diminish the visible colouring. But we have seen above the increase of distance diminishes the distortion, and, therefore, all such colouring as arises from coloured rays being unequally distorted.

W. G. Penny.

LINKAGES.

[22322.]—Readers of Mr. Marshall's paper on "Linkages" (letter 22283) will probably be interested in the following properties of his "contra-parallelogram"—properties so simple, and I should think capable of being so useful to the draughtsman, that they ought to find a place in elementary works on conics:—

A B b a (see accompanying figure) is a frame of



four links, jointed at A B b a. AB = ab, and Aa = Bb. P is the intersection of Aa, Bb; T the intersection of AB and b a, both produced.

Then, if AB be fixed on the paper, and the rest of the frame moved round it in the plane of the paper, P will describe an ellipse, of which A and B are the foci, Aa the length of the axis major, and Tp joined will be a tangent to the curve at P.

Again, if Aa be fixed, and the rest of the frame moved round it, T will lie on a hyperbola, whose foci are A and a, length of axis AB, PT a tangent to the curve at T; and the asymptotes will be parallel to AB, and b a in the two positions in which these lines are parallel to each other.

E. J. Lawrence.

BEE-KEEPING.

[22323.]—I think it not unlikely that many readers of the "E. M." either are already bee-keepers, or intend to become so next season; to those it would be a great matter if now someone who had a *good practical knowledge* of the best method of working improved bar-frame hives with sectional supers, would give plain directions for commencing operations on the approach of spring. I will suggest a few points on which I think some practical information would be very desirable. How soon would it be desirable to examine stocks to see how they were off for food, supposing them to have been packed for winter in November last with a fair supply of sealed stores, and to give them candy if they required it? How soon would it be advisable to commence stimulative feeding to promote early breeding, so as to have the stocks strong early, to take full advantage of the first supply of honey? What would be the *best* time for getting stocks which have wintered in skeps into bar-frame hives? and what the *earliest* time at which it could safely be done, and the best method of doing it? Also, supposing a person to have successfully introduced an imported Ligurian Queen into one stock last autumn, how to proceed to rear young Ligurian queens as early as possible, to introduce into his other stocks and early swarms, and in general how to proceed in order to get all his stock Ligurianised as early and safely as possible, and with the minimum risk of having them crossed with the black breed? Theoretical cut-and-dry information copied from bee books or Abbott's leaflets (which, however, are most useful in their way) is not what I ask for, as that can be easily obtained without taking up the valuable space of the "E. M.," but the result of the real practical experience of those who, having years, 69·2°. Mean rainfall for Beds, bedding, carpets, linen, any useful articles that can be packed (but not too bulky), it take. If the doctor is willing to some progressive township (not through woods and over rough tented to grow in prosperity with he may go with the assurance energetic) that he will succeed. classed as follows:—Pine lands, covered with hard woods), and these, again, are divided into first, quality—of pine, high and low lands, inland prairie, savannas the everglades. 2687.]—**Florida.**—Florida is considered to be of the most healthy of the States. The climate harming, and its beneficial influences are much ght after by invalids. Yearly it receives hun- ds of visitors, who are victims to some disease ther; the majority fixing their temporary resi- nce upon the St. John's River, and in its vicinity. ne Atlantic coast and St. Augustine, and the dian River country, are also favourite places for is class of visitors. The popularity of Florida for ck and convalescent persons can hardly be won- ered at, as the climate is a steady and compara- vely warm one. When it is cold it keeps so for me little time, and this feature of uniformity is also manifest in warm weather. It does not experience the sudden and dangerous changes that they are subject to in some of the other States, and more particularly in the north. These differences of temperature are most severe, even in the course of twenty-four hours. Perhaps it will be fairly warm and agreeable one day, and the next it will be piercingly cold. From this undesirable state of things Florida is pretty well free, as it enjoys a fairly even and steady temperature; and this, no doubt, accounts for the small number of deaths from consumption in that State. In the census reports of deaths from that disease for 1860 we find the following table of figures:—1 in every 254 in Massachusetts, 1 in every 473 in New York, 1 in every 1,139 in Minnesota, 1 in every 1,447 in Florida. The State is a wild, and for the most part an uncultivated one, the land being covered by pine forest, swamps, ditches, and here and there a lake or a river. Cattle roam about wild, and are only collected together about once every twelve months, that increase or decrease may be reported. They subsist on the wild grasses, and various plants and shrubs, which would be altogether unsuitable for dairy cows. The soil varies in different parts. In some places it is a kind of sand mixed up with shells, small pieces of rock, &c. In others, it is a dark mould, plentifully mixed with sand; but almost everywhere it contains a good supply of vegetable matter. However, when it has been carefully attended to, many things can be grown in it. For instance, new potatoes, melons, strawberries, blackberries, and several other things, all of which are sent to the northern markets, and realise a good profit. The sour orange, the bitter orange, and the bitter-sweet orange, together with the fig, the lemon, the lime, and the peach grow wild in Florida, and the sugar cane matures there. Many kinds of wild game, venison, and fish are very plentiful. Beef is supplied from some of the Southern States, and butter from the North. As to the quality of the former very important article of food, and especially to an Englishman, a difference of opinion exists. Some travellers say it is decidedly good, and others say it is decidedly the reverse. Then canned fruits and meat, ice, and many other such things, are imported. Altogether the living in Florida is much cheaper than in many other of the States. No doubt as the population becomes larger, and it is rapidly increasing, many improvements will be introduced. One of the sports indulged in is alligator shooting, and it is said to be capital amusement. Taking it as a whole, Florida is one of the most favourable States for emigrants to settle down in for many things. There are some inconveniences and annoyances to put up with. For instance, mosquitoes and fleas are plentiful, and exceedingly troublesome, and more especially the latter insect. But we cannot have everything just as we would wish for.—W. Henley Richmond.

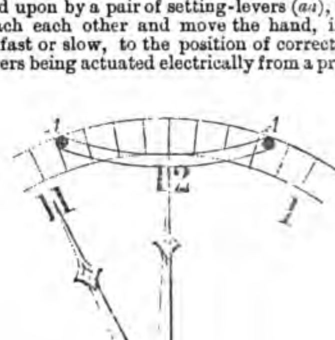
[52712.]—**Coupling Railway Waggons.**—The best mechanical tool I have yet seen is one recently patented (Graham's patent). Some are working now at Swindon and other places, giving, I believe, every satisfaction. It is made of tough metal, weighing about 8lb., and is 5ft. 4in. long. —Buffer.

[52714.]—**House Chimneys.**—I notice in my reply that there is a misprint in the last line: it should read, six times the "least" width at base.—Ditton.

[52740.]—**Drying Damp Room.**—I have had a good deal of experience in the matter of damp rooms, and I believe the only satisfactory remedy is to have the room studded inside, *i.e.*, lined with lath and plaster, leaving a space of 2in. between the plaster and the wall.—M. D.

[52751.]—**Recovering Silver.**—In answer to a "Sheffield Workman's" query, I venture to suggest a method to his consideration, though I will not guarantee its commercial, or even its experimental, practicability. Procure an electrolytic bath composed of chloride of silver, dissolved in strong ammonia. Introduce into it a cathode of silver and an anode of a bundle of the bits of silvered iron, and then pass a suitable electric current. The result will be the appearance of metallic silver at the former, and chlorine at the latter. Chlorides of silver and iron are produced, the silver compound dissolving in the surrounding ammoniacal liquid, while the iron salt is converted by it into ferrous or ferric—according to the amount of oxygen in the solution—hydrate, both of which are insoluble in the solution. A coat of this substance would tend to protect the iron from further action to a certain extent if the current is not so strong as to detach it as it forms. This action on the iron is, of course, not desirable; but, anyway, none can be deposited on the cathode till all the silver is out of the solution. I propose this method as a general plan for experiment, and if a "Sheffield Workman" should see fit to give it a trial, I should be interested to hear the result. I may add that I do not think very much net saving will result by the adoption of the method put forward by R. A. R. Bennett (page 457). From the query, it appears that the pieces of iron are ¼in. square and 1in. long, and although the thickness of the silver layer is not stated, it is not likely to be very substantial. The amount of nitric acid required to dissolve all this iron would not be inconsiderable, to say nothing of the cost of the subsequent processes he recommends. If it could be managed to use, render the iron in the so-called passive state by means of strong nitric acid, and so dissolve the silver only, while the iron remains unacted upon, the cost would be within bounds. But although I have had no practical experience with this point, I have read that it is difficult to manage. With our Editor's permission, I will briefly describe a process I started a year or two ago for the recovery of ordinary laboratory silver residues, and its advantages over the other usual methods that are recommended. The residues referred to almost always exist as chloride of silver. Wash by decantation, with plenty of water, in a capacious vessel which can be shaken, the mass—filter paper and all—till free from copper, &c. Next drain off as much water as possible, and add strong ammonia, and after a time filter to get a clear solution. Place this in a wide-mouthed bottle, which fit with a cork. Through the cork passes two wires, to one of which attach a cathode of a strip of silver, and to the other an anode of lead. Lastly, connect a Daniel cell, and leave to itself for a day or two. The strip of silver will then be found studded with crystals of the reduced metal, while the lead will have a scale of lead chloride, some of which may have fallen to the bottom of the bottle. The ammonia is then shaken up, with the remaining undissolved residue, the lead scraped, and the cell recharged, when all is again ready to proceed for another two or three days. It is obvious that a bag of the washed residues can be suspended in the electrolytic bath. It is not a process to be recommended if rapidity is an object; but this is often of no consideration whatever, as in my case. I do not, also, recommend it for large quantities, though under certain circumstances it might answer even then; but for small quantities, such as pints or quarts, I certainly do, and claim for it the following advantages:—1st and greatest. Less expenditure of superintending time and trouble than any other. The time expended in preparing the ammoniacal solution is but a few minutes. That expended in charging the cell is about the same, and besides these there is absolutely nothing to do beyond occasionally scraping the lead anode and collecting the silver crystals, after the easily fitted up and simple apparatus necessary has been procured. 2nd. Small cost of apparatus and materials. Those consumed are zinc, copper, sulphate, and lead. The ammonia will do over and over again, for the cork prevents its dissipation, and the loss in manipulation need be very small. 3rd. There is less mess and disagreeable work than any other method I know of. What little there is, is of a decidedly pleasant nature to me. 4th. The silver is obtained in a convenient form for future use, which is usually to prepare the reagent, silver nitrate. I have tried the method of reducing by means of zinc, but found these disadvantages and difficulties. 1st. It is not easy to ascertain when all the chloride is reduced. 2nd. Washing the metallic silver powder free from zinc chloride is a matter which takes a very considerable time. 3rd. The process is messy and disagreeable. 4th. The reduced metal cannot be very pure, for ordinary zinc always contains a little lead, which would remain with the silver. I have also tried reduction by means of glucose, though not very thoroughly, finding it take time and trouble. The process of reduction with carbonate of soda in a crucible is the worst of all in my estimation for small quantities. The time is greater than any others, and the heating of the crucible without special apparatus is most troublesome, to say nothing of the fuel consumed. Moreover, whatever others may find, I have always observed numerous little beads of silver scattered in a most aggravating manner all over the pot, which it is impossible to collect. I may mention that by the electrolytic method described, every trace of silver leaves the solution after a time, as may be proved by neutralising with an acid. One word more in reference to the query. It might be worth while dipping the ends of exposed iron into melted paraffin wax before placing in the electric bath.—L. S. Powell.

[52752.]—**Clocks to Strike by Electricity.**—The Standard Time and Telephone Company are the sole owners of Barraud and Lund's patents, which can be applied, at a slight expense, to any clocks now in use. Patent No. 2720: This invention relates to apparatus for synchronising clocks or other timepieces, or frequently setting them to standard time, in which one of the hands, when it reaches a certain point in its travel (say every hour) is acted upon by a pair of setting-levers (*aa*), which approach each other and move the hand, if it is either fast or slow, to the position of correct time, the levers being actuated electrically from a primary timekeeper. It consists of an apparatus in which the setting-levers are, in addition to the arms (*aa*) which clasp the clock hand, provided with cam arms, which present their opposed faces to the action of a pin, or projection, moving between them, all parts being so arranged that as the pin or projection approaches the fulcrum of the lever, the cam arms are parted, and the clasping arms (*aa*) are consequently caused to embrace the clock hand. It also consists of a weighted lever bearing the said pin, raised by the action of clockwork, and retained, when raised, by a suitable catch, and [illegible]



[illegible] accompaniment. If you want a [illegible] extended instrument, I [illegible] try to cram it into a [illegible] more room you can have [illegible] the greater will be [illegible] attaining your desired object.

[illegible] These advantages, [illegible] in favour of

QUERIES.

[52925.]—**Dissolving Leather.**—Can any of our chemical friends inform me if leather could be dissolved, and then pressed into a mould?—H. S.

[52926.]—**Double-Cell Bichromate Battery.**—Would "Sigma" explain the reason of a thick yellowish-brown mud depositing, in about twenty minutes after starting this form of battery, on the zinc plate in porous [illegible] Zinc is well amalgamated, and mud forms on it. When [illegible] is rubbed off, amalgamation still [illegible] Am using dilute H_2SO_4 in inner cell, and ordinary bichromate solution as recommended by "Sigma" [illegible] with bichromate batteries in outer cell with two carbon plates, 6in. by 3in. Zinc 6in. by 3in. Have used dilute H_2SO_4 1 in 12, and half saturated solution of $ZnSO_4$; but with above result. Otherwise this seems a good form of battery, as it is more constant than single fluid bichromate.—[illegible]

[52927.]—**Watchwork.**—I have an English lever watch come to me to repair which has been to three or four men in the trade to repair, and they have failed to give satisfaction. I have been in the trade for about four years, and have not learned everything yet, and would like to do this job. When I wind the watch to the top, the action of the balance is nearly at a standstill, but when the watch has run half-way down the action is splendid, and keeps good time. A remedy would oblige.—PERPLEXED ONE.

[52928.]—**Copperplate Printing.**—Will some one give me the name of an ink, paint, or varnish that will print well from copper plates, and stand the action of aqua fortis? Also a recipe for making a transfer paper, so that patterns, when printed, may be transferred to a flat surface, and paper be removed.—H. B. H.

[52929.]—**Engine Query.**—Thanks to "Labor Omnia Vincit" for his last reply. They are a pair of non-condensing engines: 21in. diam. cylinders, 3ft. stroke, 70 revs per min., and work at a pressure of 5[illegible]lb in boiler.—ENGINEMAN.

[52930.]—**Filter Presses.**—Will some correspondent oblige me with particulars of the best form of above for separating a very bulky precipitate which it is required to wash well? It will be necessary to reserve both the precipitate and solution for subsequent use. A rough sketch, or any details, will be very useful.—FERRO.

[52931.]—**Anotta.**—I wish to make my own fluid extract of anotta to mix thoroughly with milk, butter, and cheese; but I do not know what quality of anotta is used: Is it roll, or are there any others, and what is it dissolved by? I have two samples beside me: One is a dark fluid, the other is a red fluid: but I prefer the red quality, as it mixes better and goes furthest, and produces a richer tint.—FLUID.

[52932.]—**Delirium Tremens.**—Can it be explained why persons suffering from the above malady always have the horrible depicted upon their mind's eye, and never anything pleasing? There must be a reason. Is it known?—CYMRU.

[52933.]—**Timeball.**—Having made timeball to fall by electric current (from kind instructions of Mr. Baldwin), I am at a loss how to get it in position again. Can I wind it up in any way by electricity? Will "Sigma" or Mr. Lancaster oblige?—W. JONES, 78, Viaduct-street, E.

[52934.]—**Lantern.**—Could any of our readers who have had experience with magic-lanterns give me information on the following points? Is there any lantern made that will show ordinary 3in. by 1in. microscopic slides satisfactorily? If so, can they be shown with petroleum lamp, and what sized discs will a 2in. and a ½in. objective throw on the screen, respectively? I want to give some demonstrations of microscopic objects in a country village to an audience of, say, 100 people. Any hints will oblige.—M. D.

[52935.]—**Legal.**—Would any legal friend oblige me with the reference number of the statute which makes a man liable for the maintenance of his grandchildren?—O. RUSSELL PRIDHAM.

[52936.]—**Small Siemens Dynamo.**—I am just completing a Siemens H dynamo—a 6in. by 2in., 1½lb. No. 18, F.M.'s 5lb. each No. 14 copper wire. I wish to know what is the least external resistance I may use without unduly heating the coils. Are the magnets reckoned with external or internal circuit—the machine being series wound?—A. W. LAMBERT.

[52937.]—**Ancient Lights.**—I am about to erect a building in my back garden 35ft. high, at a distance of 20ft. from the back of the house; but am afraid it may injuriously affect the light of my workroom, and also back parlour. The workroom is on the level of the garden, and the window is of an ordinary size. The light is not derived from the sides, but direct from the back. The parlour is above the workroom. Would this arrangement be likely to materially affect the lighting of those two rooms?—DENTIST.

[52938.]—**Heating of Journals.**—Can any of "ours" explain the cause of heating in journals when shaft is well bedded, true, and running without load at 400 revs. per minute? Diameter of shaft is 6in., and as soon as one neck cools another starts getting hot. I have tried all kinds of compositions, but all are useless. At 300 revs. per minute, however, the shaft runs well.—APPRENTICE.

[52939.]—**Binocular.**—When I look at the sky through a binocular bought from a maker of highest repute, a central darker area, and round it a lighter marginal ring are seen. If a radius be taken, the former occupies about two-thirds, and the latter about one-third. The defect is in the eyeglass, as is ascertained by looking through it separately, and it does not depend on reflection from the inside of the tube. Blackening the outer edge of the eyeglass has not effected any improvement. Can any reader kindly say what is the cause of this defect, and whether it is inseparable from binocular eyeglasses, or in what way it can be remedied?—I. C.

[52940.]—**Gas Stoves.**—Will Mr. Fletcher kindly say a few words in explanation of the corrosion of gas-[illegible] as [illegible] and as [illegible] remedy? [illegible] or rather eaten away, in less than six months. It was made of the [illegible] I have now replaced [illegible] copper [illegible] and the [illegible] the same way.—[illegible]

[52941.]—**C.R. Engines.**—[illegible]

[52942.]—**Converting Sewing-Machine into Fretsaw.**—[illegible] a sewing machine [illegible] make a fretsaw without [illegible] trouble and expense [illegible] well? Then how would I get the saw perfectly [illegible] a better plan?—[illegible]

[52943.]—**Electro-Magnets.**—[illegible] with the armature [illegible] both poles of the magnet [illegible] sticks to the magnet when the current is released. In an apparatus I am constructing I want the armature to be in actual contact with the electro-magnet, but want to prevent the sticking of the armature when contact is broken. Can this be done without sacrificing the holding power of the magnet? When the armature touches only one pole of the magnet it drops off only when the current is stopped, but I want to utilise all the holding power of the magnet, and yet be free from the sticking armature when the current is released.—[illegible]

[52944.]—**To Mr. Wassell.**—Will Mr. Wassell kindly advise me how to correct a mirror I have ground and polished? I have compared it under the same test with a [illegible] mirror I possess of Calver's. The appearance of mine is the same as Mr. Calver's, only more so, so I judge it to be hyperbolic. It is without rings, but in various directions across the face of the mirror I see straight lines, which I can in no way account for, and it is with regard to them that I should be grateful for Mr. Wassell's opinion.—[illegible]

[52945.]—**Oxidising Copper Wire in the Battery.**—What is the reason that the copper wire oxidises in the battery? Also, if there is any way to stop it? We use salammoniac and copper wire to connect the bottles.—"E. M." READER.

[52946.]—**Lightening a Wife's Domestic Duties.**—I should be extremely obliged if some correspondent would devise some simple and inexpensive little pump by which a lodger could raise the water necessary for his wife's domestic consumption, about two gallons daily, from the cistern of the house, which is situated about 12 or 14ft. below the window of his living room. No fixtures to cistern would be allowed.—A PERPLEXED PARTNER.

[52947.]—**Spectrum.**—Having been studying Mr. Lewis Wright's admirable book on "Light," I recently attempted to produce the spectrum by means of a bisulphide of carbon prism. As it was a private experiment, I did not take the trouble to prepare gas, but used a powerful oil light. Although I put a slit in the lantern stage [illegible] by [illegible]in., and generally followed the directions given, I could not get the band of colour. I tried with and without both condenser and object lens, and also interposed a biconvex lens of [illegible] focus between lantern and prism; but still without success. The dim band of dispersed light produced showed no colour whatever. In my perplexity I turn to the "E. M.," and beg to say that I shall be grateful to any kind friend who will point out what was wrong in my proceedings, or, better still, indicate the right method of obtaining the desired result.—W. HOBBS.

[52948.]—**Banjo.**—Could any of our readers kindly inform me 1, the best tutor for a six-stringed banjo, and the publisher of same? All the tutors I have seen treat chiefly on the five-stringed banjo, and say practically nothing about the six. 2. What sized strings should be used for a six stringed banjo? 3. In striking the notes with the thumb and forefinger of the right hand, should the tip of the forefinger be farther from or nearer to the bridge than that of the thumb?—P[illegible]

[52949.]—**Length of Cord.**—An acre of ground contained within a complete circle. Required the length of cord that will exactly sweep half an acre of the same when attached to a stake at extreme edge of circle?—J. B.

[52950.]—**To Violinists.**—Having lately begun the study of the violin, I want to ask advice from "those who know" on one or two points. I have been much annoyed by constant breaking of strings, and this I think I have traced to perspiring fingers. Is there any remedy for this, or anything which could be recommended as likely to modify the evil, if not quite to obviate it? Then I find that my hand, and especially my little finger, is so ridiculously short that I cannot by any means reach B on the first string, not to speak of D on the fourth, without shifting my hand. Is there any exercise or method of stretching the hand which would be of use? I may say that I am 25 years of age, and will be content with a very moderate proficiency; and perhaps my joints may be too stiff to enable me to get over these difficulties at all.—BEGINNER.

[52951.]—**Smiths' Forge.**—Would some practical person kindly instruct me the best way to fit up my forge for general country work, both light and heavy, as I can't get on with the one I have now? I have tried different ways, but can't find the right one. The forge burns a lot of coal, but always makes the iron so rough with scales and clinkers that I have to scrape or file it. Is it the fault in the tue-iron in fixing it? I have one at it with a ¾ hole in it. The bellows is a large one, and I use Welsh coal. Could some one kindly instruct me how to make a simple perpendicular drilling machine to drill up to ½in. holes?—YOUNG COUNTRY SMITH.

[52952.]—**Loss of Voice.**—Will some correspondent kindly advise a beneficial remedy for this distressing complaint? I have no cough, throat not sore; and I am to having got very wet in the feet for some days— month since. Have tried several remedies. and 'erent doctors have prescribed—but to no purpose. seen good results from answers for different ailin "ours," I hope to derive some benefit from ho may have suffered similar.—M. L.

3.]—**Latitude and Longitude.**—To "O. V." .ERS.—Is there any rule by ordinary arithmetic it algebra) to find the number of English miles ed, when the number of degrees is given in latiad longitude, and what difference in reckoning ıe first or second meridian is given?—CYPHER.

4.]—**Hand Water Tap.**—I require frequently w a variably continuous gentle stream of water ticles held steady by the left hand, and which canveniently be moved about. I am thus left with e hand free to control the water supply, and 'eel much obliged if any of "ours" will tell me construct a small, simple, and inexpensive hand attachment to a ⅜in. elastic tube connected to verhead cistern) by which, whilst held in the right could, say, with the thumb or any of the fingers, or off the water at pleasure. The perforation at z e need not exceed 1-16in. in diam., and there ittle or no water pressure, the hand tap does not to be of any great strength.—ARNOLD WARBUR-

5.]—**Tiles.**—What should be done to re-establish of blue quarries which have been made light by used in setting them? The cement has been over surface for filling joints.—CLAY.

6.]—**Dyeing Furs.**—I am desirous of obtaining nt information to enable me, as a dyer, to dye the ıcks and browns used in present fashion on sealnd other furs.—JAS. CHALMERS.

7.]—**Hydraulic Lifts.** — Will some reader describe the construction of those small hydraulic ıich I have seen used for getting big guns into ı?—JASON.

8.]—**Ancient Lights.**—It is desired that some ildings in the course of erection shall not encroach he legal 45° line of light of the neighbouring An argument has arisen as to how the 45° is to ıd. One says that the proper, practical, and techlan is, that if the wall to be built is 15ft. high, its ust approach the neighbour's back within 30ft.; r says that wall being 15ft. high, the approach may ear as 15ft. This seems to me to be correct; as in case 15ft. perpend. 30 base, a right-angle triangle use hypoth. to subtend from top of wall an angle , the complement being 22½°; while in the second rpend. and base 15ft. each, right-angle triangle will ypoth. to subtend from either point angles of 45° GREEK.

9.]—**Beer in Scratchbrushing.**—What can s a substitute for beer in this process? Will anynswer so well?—W. H. H.

0.]—**Plate Machine—Silk Flaps.**—How are ps attached to rubber, and what kind of oil is used hem? Should there be more than one thickness of My reason for asking is that when I used black ed with flask oil, instead of a gain, I found a loss er.—W. H. H.

1.]—**Butterflies.**—Will some kind entomological pondent help me in my difficulty? I have had a ase of butterflies sent to me from Nepaul, but the are closed and rigid. I want to open them. I have team and moist sand, both of which are tedious think, injurious to the plumage. Are there no ds rapid and safe?—LU.

52.]—**G.W.R.**—Can any reader oblige me with ılars of No. 55 Queen, single? Also Nos. 483, 490, 8, all 4-c.—T. M. R.

3.]—**Weight of Coaches.**—Can any of "ours" me with the weight of six and eight-wheel s, now in use on the principal railways?—T.

4.]—**Medical Coil.**—I made one with three f No. 22 for primary, and six rows of No. 36 for lary. I found it take a strong current to work it, t much power then. Thinking if I had less resistı primary, less battery power would work it, I unl and put two rows of No. 16 as primary. I still will not work with less than one cell of bichromate of Smee. Two cells of Fuller, or two of Daniell, t work it. They do not seem to magnetise the core ently. Core is No. 18 very soft iron wire, and when power enough to magnetise it, I get a very powerondary. Had I better go back to the No. 22, and ave two rows? All the layers are well insulated paraffin. I have made a very satisfactory primary ter Mr. Fred. Walker's pattern (but a little larger), ıis works with one cell of Fuller or one of Daniell, quires a water regulator to modify the effects. I my secondary coil to work with as little an amount tricity as the other one.—J. E. A.

65.]—**Regulator for Shocking Coil.**—Will f our readers kindly inform me how to make ılator for a shocking coil 7in. long?—No. 16 cottond wire primary, No. 36 silk-covered for secondary. ɪGO.

966.]—**Strength of Spring.**—Would any of readers inform me what strength of spring steel I I require to make, so that a man could just wind th a windlass 2ft. 6in. long—i.e., a stroke of 5ft.? what length of spring I should require to continue rce equalling the man's strength for two, four, or urs?—E. M. B.

67.]—**Hydrogen Peroxide.**—Will some of your cal contributors have the goodness to furnish me a few particulars upon the preparation and proper- hydrogen peroxide? The subject is referred to in rrent issue of the *Jour.* of the Chem. Soc., p. 226, o briefly to be of much assistance. The points on I seek information are—(1) A practicable mode of mically preparing hydrogen peroxide? If not cont in a small laboratory, say if the barium xide can be procured ready made, and how the gen peroxide is prepared from it? (2) Ch. of lime is understood to be soluble in 10 parts of water, a given measure of which furnishes a measurable quantity of available chlorine as bleaching or oxidising agent. Now state in what proportion the soluble hydrogen peroxide is soluble in water, and the oxidising power in comparison with an equal quantity of the 10 per cent., or saturated, ch. of lime solution, and also with a solution of potassium permanganate of known strength? (3) Supposing that the hydrogen peroxide proves to be feebly soluble in water, is there any other menstruum in which it can be stored up in a concentrated and available form? (4) Are there any known means of economically preparing ozone for employment as an oxidiser in concentrated solution?—AMATEUR.

[52968.]—**Slide-Valves.**—To "ENGINEER," OR "FIRER, Dewsbury."—I have several books on the steam engine, but I cannot find in any of them the formula for the proportions of lap and lead for slide-valves, such as are necessary for answering questions set by the Science and Art Department. As an example of such, "The lap on the steam side of a slide valve is 1⅛in., that on the exhaust side is ¼in., and the lead is ⅛in. Find the opening for exhaust which the valve will give at the lower part when the piston is at the top of its stroke." I would like it wrought out in arithmetic, also the formula with it.—FORMULA.

[52969.]—**Chloride Battery.**—What is the best form of charging this battery (for bell work only)? If I had two sets of porous pots, one set being kept soaking, whilst the other was in use, would they become sufficiently clean in the pores, or nearly as good as new?—R. HANNEN.

[52970.]—**Cup Leathers for Garden Engines, small Plunger Pumps, &c.**—Will any reader kindly tell me the best way of making these? I have a lathe.—AQUARIUS.

[52971.]—**Antimonial Lead.**—Will any one of our chemical readers give me an easy method of ascertaining the quantity of antimony in an alloy of that metal with lead containing, say, from 5 to 20 per cent. of antimony? My knowledge of chemistry being very limited, I should require plain instructions. I fancy a method by volumetric tests would be very convenient.—GALENA.

[52972.]—**Turning Stone.**—Having a turning lathe' power, and wishing to turn a few small circular sandstone pillars, would "J. H.," or any of "ours," kindly inform me if I would require to put iron centres in them, and if the tools used for turning iron would do? Also if the tools require oil or water during the process, and some information as to putting the best polish on the pillars when turned?—GEORDY BLACK.

[52973.]—**Sharpening Circular Cutters.**—In a science textbook that I have ("The Strength of Materials," by John Anderson) the following words occur:—"It is not many years since it was deemed impracticable to sharpen hard steel circular cutters without first softening them; yet we now see that it can be done as easily as sharpening a drill at the grindstone, and by an arrangement as old as the cutting of diamonds, and upon the same principle." I should like to ask some of your numerous correspondents to kindly explain the arrangement alluded to, and oblige?—A. SUGDEN, Leeds.

[52974.]—**Pyro-Hydrogen Light.**—In Mr. Chadwick's "Lantern Manual" mention is made of the pyro-hydrogen limelight. Will Mr. Chadwick, or Mr. Lancaster, please tell me if this light is a success? The light is produced by a stream of hot air and hydrogen impinging on a piece of lime, which it heats to incandescence. Also tell me if common house gas could be used instead of hydrogen. If I am not asking too much, I should be glad to have a drawing of the most approved form for lantern purposes, I shall be glad to see query 52897 fully answered. It would be an easy matter for any reader who has the slides named to explain their motion, &c.—GRAPHO.

[52975.]—**Oven for Malleable Castings.**—Will any reader give me a sketch and description of the ovens used in foundries where malleable iron is made for keeping the articles hot for three or four days together? I have tried to get books giving sketches of these ovens, but failed. A sketch is necessary.—J. H. B.

[52976.]—**Bleaching Horsehair.** — I want to deprive black horsehair of its colouring matter, and produce a white or yellow, without destroying its elasticity or burning it. I have tried hydric peroxide and chloride of lime, without success. Is heat necessary? Replies in back numbers have all been tried. The advice of our chemical friends will much oblige.—D. GAMMIE.

[52977.]—**Hydraulics.**—(1) What would you consider to be the right sort of test to discover the cause of the failure of a rising main? (2) What reason could you give why a pipe (any size over 2in.) will not run full bore with any head over 6in.?—J. DURHAM.

[52978.]—**Dynamo.** — Would "Sigma," or some other correspondent, kindly tell me if a Siemens compound armature has any advantage over the simple H form for incandescence lamps, and if so, I should be greatly obliged for working description of mode of winding a compound armature, with proportions of wire for small machine with magnet 10½in. high, length of pole-pieces 5½in., core on which to wind wire 5½ by 4 by ⅞in., width between centres of cores 3in., armature 5½ by 2¼in. Also what would be the best way to wind magnet, series, shunt, or compound, for incandescent lamps?—J. P. M.

[52979.]—**Railway Keys.** — I shall be glad to know the opinion of your engineering correspondents upon the position of railway keys. The Midland Coy. have, for years, placed the keys inside the rails. Last week a great change was made, and for the future the keys are to be placed outside. Can any reader tell me the actual cause of this important alteration?—as doubtless a company would not go to this great expense without some reason.—HISTORIAN, M.I.M.E.

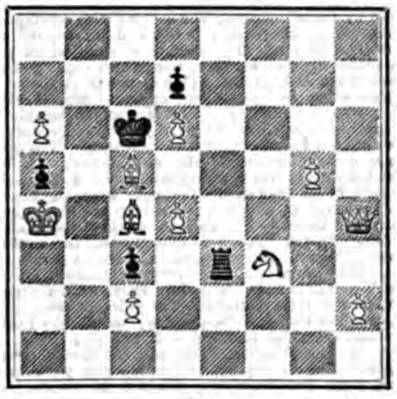
[52980.]—**Crescent Moon.**—A friend of mine saw the moon with the naked eye shortly after six on the evening of the 29th ult., when our satellite was not 38 hours "old." Would any reader say whether this is noteworthy in our wretched climate, and also state the "youngest" moon that has been seen with the naked eye?—ARTHUR MEE.

CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Bryn Rhedyn, Llandwrog, Carnarvon.

PROBLEM DCCCLXXIII.—By SERGT.-MAJOR McARTHUR.

Black.



White. [11+5

White to play and mate in two moves.

SOLUTION TO 871.

White.	*Black.*
1. P to Q 6	1. Anything
2. Anything	2. Q mates

(4 variations.)

NOTICES TO CORRESPONDENTS.

CORRECT Solutions to 870 by J. B. of Boxford, F. Renney, Dicky Sam, and T. H. Billington; to 871 by Rev. W. Anderson (Old Romney), W. H. Evans, A. Schmucke, J. G. E (Sittingbourne), J. B. of Boxford, E. S. Follwell (Bristol) (weak; no scope for Black), Dicky Sam, T. H. Billington, F. Renney, and D. Millar; to 869 by A. Schmucke (second solution); to 868 by F. Renney.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, Feb. 6, and unacknowledged elsewhere:—

J. P. STRANGMAN.—Crossley Bros.—J. Mackay.—J. Hargreaves.—C. Nickalls.—G. W. Healey.—E. W. Spofford.—P. A. Ransom.—T. Massa.—H. Lovegrove.—W. A. Smith.—J. B. Yonge.—C. E. Fison.—F. H. Smith.—M. Taylor.—E. M. Nelson.—M. A.—One in the Trade.—Eothen.—Organic Chemist.—H. C. B.—Corrigenda.—H. B. T. Strangways.—F. W. Brewer.—W. G. Penny.—T. R. Clapham.—Fred. Carre.—C. E. B.—C. Detaille.—D'Elgo.—R. T. Lewis.—A Fellow of the Royal Astronomical Society.—S. Bottone.—M. Y. C.—C. E. Stretton.

AN HUMBLE READER. (So far as we understand your query, we should answer it by the question, Why should it be?)—A YOUNG LITHO. (Many recipes in back numbers—actually one on p. 457. The liquid in the streets is solution of nitrate of mercury, which will spoil anything to which it is applied.)—TELEPHONIC. (The "rule" is a calculation of the total resistance and the quantity of current required compared with the known E.M.F. of any given cell. Do not understand about the commutator. Surely it has that already.)—P. E. GATES. (Yes to both questions; but if as a motor, how will you drive it?)—QUILLDRIVER. (Can only be done by careful measurement and frequent trial as work proceeds.)—CRACK IN BOILER. (Frequently answered. The proper cement is that made of iron filings, sulphur, and sal-ammoniac; but it requires some skill to use it in such a situation, and it would be cheaper to have a new boiler.)—ENQUIRER. (Doubtful if there are several works on the subject; but try the list issued by Mr. Hastings, 22, Buckingham-street, Adelphi, W.C.)—BROTHER STIGGINS. (As no one has made such a machine, how is it possible to say what it will do? We have no space for "notions" of that kind. If you want a dynamo, make one to the pattern given in these pages.—W. P. W.: Waves of Kiev. (You will find illustrations in Vol. XXX. p. [illegible], Vol. XXXI. p. 3[illegible]1, Vol. XXXV. p. 5[illegible], Vol. XXXVI. p. [illegible]03, all with illustrations.)—Scott & Hart. (Mix whiting with the [illegible], but if a very high temperature is reached, whiting and boiled linseed oil (putty) make a good lute. [illegible] and [illegible] low will stand almost anything.)—[illegible]. (You cannot adopt another man's crest, but you will have to apply to the Heralds' College, Queen Victoria-street, E.C.)—Shad. (It gets in by means of a valve—the snifting valve.)—[illegible] N.E. (It should be examined by a medical man, but bathing with solution of permanganate of potash, Condy's fluid, will do no harm.)—A Novice. (Try acetate of iron, which you can make by steeping iron filings in vinegar.)—[illegible] Olson, Clear Lake, Iowa. (We do not think that it is still on sale; but you could apply to Mr. Wesley, Essex street, Strand, London. He might be able to procure you a copy. 2. Why not send here for one, as many of your fellow-countrymen have done. The duty is not quite prohibitive.)—E. J. [illegible]. (1. We cannot say what the company would do. 2. A speaking tube would answer, if there were not many bends. 3. That could be easiest answered by the surveyor to your local board.)—[illegible]. (A work of the kind is advertised in the "Sale" column the last two weeks.)—James T. Webb. (See the indices of back volumes.)—J. B. (They are not. Saunier's "Watchmaker's Handbook," published by Tripplin, Bartlett's-buildings, E.C., is the most suitable. The price is, we think, 12s. 6d. For books on "Carpentry," see Crosby Lockwood and Co.'s list, and that of E. and F. N. Spon.)—J. A. Ryde. (Thanks. You will see that a correspondent has already replied fully, and we cannot afford more space for a subject which is, after all, of little interest to the majority of our readers.)—N. B. (It is, as its name implies, mashed paper. The majority of articles are made of the pulp before it is converted into paper. You can easily try by stewing some old paper until it can be pressed into a solid block.)—Nimrod. (The bottle query is an advertisement, pure and simple.)—Ajax. (You will find several recipes of the kind by searching the indices.)—G. M. [illegible]. (You may go on scraping until doomsday, and you will never get *two* blocks to a true plane. Scraping is right; but you must have *three* blocks to check one another. See the Whitworth Papers, in Vol. I. of which you will find the art of making true planes fully described. Every mechanic ought to have those Papers.)—X. Y. Z. (No, a siphon will not answer where the height to be lifted is greater than, say, 30ft. It depends on the weight of the atmosphere and the height of a column of water which it can support.)—C. E[illegible]. (No doubt some one will offer to repair it, if you advertise your address.)—H. E. J. (He described his magnesium lamp on p. 277, Vol. XXXVI.)—Battery. (Draw the magnet several times over it while the current is passing, but always in one direction. It is better to use a coil of wire.)—Advertiser. (The query has been frequently answered. For all the use they are, methylated spirit would do as well.)—Southport. (They are out of print now; but you would find much information by looking through the back volumes.)—[illegible] W. (They will do, but are nothing like so good as the proper lenses. You should read the papers on "How to Make a Magic Lantern" in the back volumes. See recent replies about the developer.)—[illegible] B. [illegible] (Plenty of devices of the kind in back volumes. The very thing that you think will suit you was illustrated on p. 524, No. 990.)—James Eastwood. (We are unable to find the points of novelty in your description, because you do not give them. We should [illegible] a shaft, with a wheel of that weight on, to run as [illegible] as you say.)—Devonshire Reader. (Will [illegible] a trial, and make a note of it.)—F. J. [illegible]. (We really do not know: it would make [illegible]. The bob would have to be pushed up at [illegible] a seconds pendulum at St. Thomas (very [illegible] the Equator) to [illegible]in., and at Hammerfest [illegible]. It helped to prove the lesser attraction. You should read the subject in any good text-book. [illegible] is called centrifugal force comes into [illegible] very different at the Equator to what it [illegible].)—S. J. F. (See p. 1[illegible]6, Vol. XXXIII. [illegible] over a piece of whalebone with [illegible] and use warm water and soap, rinsing [illegible] to clean the mercury, pour over it a solution [illegible] acid and water, about 1 to 5, stir, and [illegible] then squeeze the mercury [illegible] filter, or if it looks clean [illegible] two or three times.)—[illegible] the bronchitis is concerned, you [illegible] conditions there, and the voyage [illegible]. We cannot advise as to emigra[illegible] communicate with the agents-general [illegible], 3, Westminster-chambers, [illegible] difficulty about the money. [illegible] with any London banker, who will [illegible] on a bank where you go.)—[illegible] pure is used only for chemical [illegible]. (You can procure [illegible] warehouse, and will find a [illegible] in Vol. XXX. pp. 4[illegible], 4[illegible], [illegible] numbers.)—J. H., Burnley. [illegible] in No. [illegible], and some[illegible] volume, but as a matter [illegible] requires a deal of practice.) [illegible] turning, and a good deal [illegible]. There is a diagram of a [illegible].)—Markham. (Con[illegible] Lyell's "Principles [illegible] Vol. XXIX.)—Jennings. [illegible] will cure it, but [illegible] depends on circumstances.) [illegible] No [illegible], for method of [illegible] frequently answered. 2. [illegible] equations, but must have [illegible] to which it [illegible] that all sorts of hints [illegible] the best arrangement [illegible] the surrounding mould [illegible] be as effective as if [illegible], Glasgow. (We [illegible] require advice, and [illegible] competent to give [illegible] manipulation. You should, in the circumstances, write to the aurist, and tell him what has happened.)—Blowpipe. (Thanks. We are afraid it would not be appreciated.)—Amateur. (Do you not understand that it would be necessary to make one of that size and experiment with it before your question could be answered. You can obtain a good deal of information from back numbers.)—Binder. (Try again. How can they become straight if you glue up and allow them to dry?)—John Hale. (The makers might be able to answer the question; but no one else can on data so meagre.)—W. Jones. (Battery-cells are not comparable in that manner; it depends on what they have to do. Daniell's, Fuller's, Leclanché's, and some others.)—D. and W. (You will find a description of the Ross battery on p. 260, last volume; or, if that is not sufficient, a full account can be seen at the Patent Office Library.)—Naphtha. (You must explain more definitely what you mean; if miner's safety-lamps, gas must be used.)—Mechanic. (The method of magnetising steel has been frequently given. You can use either permanent magnets, or a coil of wire through which a current is passing. Bessemer steel would be better than that mentioned.)—T. A. C. (Directions for making electro-magnets have been frequently given, also electro-magnetic engines. See the indices.)—J. B. Jack. (If you cannot make either a Wimshurst or a Voss machine from the instructions given recently, we do not see how anyone can help you, except by making it for you. We cannot spare the space to give working drawings of every detail.)—G. H. S. (Glue one part, glycerine four parts, whiting quantum suff. Some use more glue. A little carbolic acid is a preservative addition.)—Phos. (The query was due for insertion in the unanswered list week; but you will see by p. 475 a correspondent has partly answered it, and called direct attention to it. Consequently, it will not be worth while to insert amongst the unanswered. If no notice is taken now, it will be better to insert another query.)—W. B. (We are as wise as ever. A jet of steam turned into a smith's fire would put it out. If you have seen it done, surely you can give more particulars, and say definitely what it is you want to do. We cannot pretend to remember all the queries we receive.)—Edward C. Corin. (Having passed an examination in chemistry, we believe; but why not write to the secretary.)—Donald M. Warren. (There is a polariscope on p. 175, Vol. XXVI., and some articles on it in Vol. XXXI. pp. 538, 561. Also many other places in back volumes. 2. Yes; several.)—W. J. Rendell. (The subject has often been discussed. See indices to back volumes, or p. 421, Vol. XXXII.)—G. Downs. (On the contrary, we think there is a good deal about it, though perhaps not a series of articles. We are bound to cater for the greatest number, and a special subject like that interests but a few, and those few are already provided for in a book issued by Crosby Lockwood and Co. As a rule, we prefer subjects that cannot be found in cheap text-books.)—Longworth. (Yes, that would do; but as you are sure to desire a bigger by-and-by, you might buy it at once. We cannot undertake to advise between a refractor and a reflector. Cannot you manage to have a trial of both, and see which you like best? As to the atmosphere, plenty of good work can be done in London. You would gain much information from a perusal of back numbers.)—Auntie. ("Small doses" is all that was mentioned. The druggist will tell you the proper quantity. It was given on p. 512, last volume.)—Pen. (It is logwood stain, made by boiling a pound of logwood for about an hour in three quarts of water. Then add an ounce of salt of tartar. Give two or three coats hot, and put in the graining marks with a brush and a strong solution of green copperas.)—G. R. Carmac. (You might get them off with a disc of copper, the edge of which is anointed with fine emery and oil; the disc to be run at a high speed in the lathe.)—A. S. Edmunds. (Yes, so it is said; but very little is known of it.)—McArthur. (The curtain might answer, and so might wires; but nothing definite could be said without at least having some idea of the size of the hall.)—J. H. (We should think not. A dynamo must have an engine that is always its master.)—Cinder Hill. (You are too late. The designs were all in some weeks ago. 2. We do not understand the difficulty.)—J. Durham. (The *Miller* is published weekly by W. Dunham, 69, Mark-lane.)—M. Rellum. (They put a little wax in the starch, and use a polishing iron.)—Student. (See the articles now appearing and back numbers. It is impossible to insert all the queries about dynamos, or the replies that might be received in answer.)—Moulder. (See previous answer.)—Investigatrix. (How can we say without seeing the examination paper? 2. The easiest way is to take lessons. Apply to the music dealers for instruction-books. 3. Advertise them. Dealers have to keep them a long time, so they cannot afford to give much.)—E. E. P. (See pp. 25 and 376, present volume. If the invention is perfected, it is better to send in complete specifications at once.)—Harry Ambrose. (Nearly every grammar contains sufficient. There are very few rules. 2. It depends entirely on the size.)—Dough. (Any oven-builder will give you the required information. You do not say what size you need; but as a guide, you can reckon that a good eight-bushel oven will cost about £30.)—Cypher. (Nothing very novel in your device; but it does not follow, because it suits you, that it would answer in all circumstances.)—A Cornishman. (In any case, it is only a matter for a civil court; X. cannot be "punished," but you may sue him and recover if your story holds good.)—R. D. (The father must administer; he had better employ a solicitor, though it is not absolutely necessary.)—Legal Puzzle. (Exactly. Who *is* the next of kin? That is the point which stands in the way of a good many other divisions of property similarly left. We cannot tell you.)

Boswell. (Duplications of letters sent to other journals are not desired.)—H. A. C. (Perry and Co., Holborn Viaduct; we believe they send samples of the material post free for one shilling.)—A Pit Lad. (His occupation, of course, varies. You had better get into an office and work hard, and then select the branch you like best. As to books, send to Lockwood and Co., 7, Stationers' Hall-court, for a catalogue, stating what you want.)—[illegible]. (Of course, the judge was right. People who trust anybody cannot expect the protection of the criminal law.)—A Poor Inventor. (There is only one way, the one you mention, and a patent is cheap now, but previous attempts in the same direction are numerous, and you would do well to search carefully at the Patent Office to see that you have not been anticipated.)—Iolanthe. (We know no such address.)

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 13s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India via Brindisi, 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 15s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The paper will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number last issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. XXIV., XXVII., XXVIII., XXX., XXXI., XXXII., XXXIII., XXXIV., XXXV., XXXVI., and XXXVII. bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in March and September, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 3d. each. Post free 3½d. each. Indexes to Vol. XI. and to subsequent vols. 2d. each, or post free, 2½d. Cases for binding, 1s. 6d. each.

CHARGES FOR ADVERTISING.

	s. d.
Thirty Words	[illegible]
Every additional eight words	[illegible]

Front Page Advertisements Five Shillings for the first 6 lines, afterwards 9d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than [illegible] insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

	s. d.
Twenty-four words	[illegible]
For every succeeding Eight words	[illegible]

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

	s. d.
Sixteen words	[illegible]
For every succeeding Eight Words	[illegible]

*** It must be borne in mind that no Displayed advertisement can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions, and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement and charged for.

Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists, London."—Also makers of Epps's Chocolate Essence.

Holloway's Pills.—This incomparable Medicine increases the appetite, strengthens the stomach, cleanses the liver, corrects biliousness, purifies the system, invigorates the nerves, and re-instates sound health. A single trial convinces the most sceptical that no medicine equals Holloway's Pills in its ability to remove all complaints incidental to the human race.

OUR EXCHANGE COLUMN.

◆

The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.

◆

Patents for Inventions.—Webster's, Agnew's and other Works wanted: for several years "Punch."—Apply J. Mason, Patent Agent, 65, West Regent-street, Glasgow.

Galvanised **Clothes Wringer**, best indiarubber rollers, cost 30s., what offers, nearly new.—H. Clayton, Colchester.

Sewing Machine, C. Howe, for leather or cloth, cost £8; No. 2 Thomas, £9; open to offers of exchange, or at one-third of cost.—H. Clayton, Colchester.

Lathe, 2ft. 6in., strong planed gap bed, with dividing plate and index; exchange value £4 15s. Strong stand, 4-speed wheel, £2 10s.; what offers.—Clayton.

Fretsaw and Lathe combined, cost £5 5s., and equal to new; cash £3 18s., or exchange to £4 15s.—Clayton.

Fretsaw, cost, with box, 19s. 6d., very little used, 12s. 6d.; or exchange to 16s. Any of above on approval.—H. Clayton, Colchester.

About 50 Magic-lantern **3¼ Slide Views**, &c., would exchange for good condenser.—Address, [illegible], Renfrew-street, Glasgow.

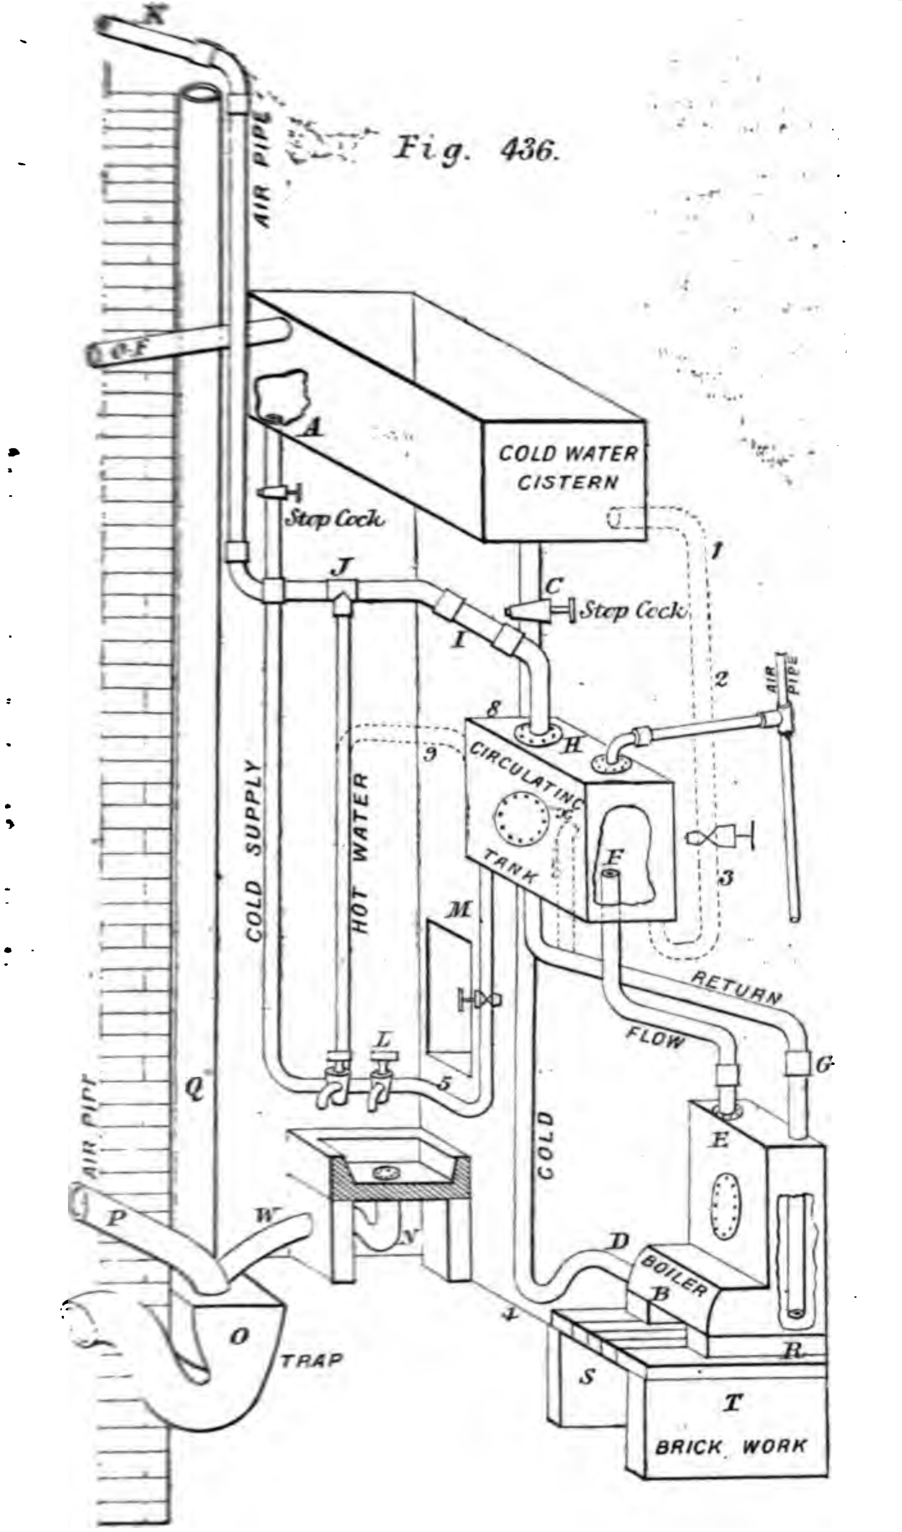
"**Blackie's Comprehensive Atlas** and Geography of World," 10 Divisions, 6s. each; 22 parts "Universal Instructor." Exchange photographic goods or [illegible].—Geo. Weatherall, Lochee, Dundee.

Zuccato's **Papyrograph**, 300 to 500 copies from one original, in good order, requires ink only, cost 115s. Exchange.—Dickson, 8, Morpeth-street, Liverpool.

Tool Chest, equal to new; offers in small lathe, pair of headstocks for small do., and flywheel.—E. Floods, C[illegible], Wilts.

Chemical Apparatus wanted for analysis and assay, in exchange for photographic or electrical apparatus.—E. H. Davies, Ebnal Lodge, Oswestry.

"**Designs for Cottage and Villa Architecture**," by S. H. Brooks, complete in 37 parts; containing plans, elevations, sections, perspective views, and estimates of the cost of erection. Exchange for lathe-heads and rest.—J[illegible], Market-street, Cambridge.



supply pipe M to the top of the hot water tank, and branch it into the top *corner* of the tank at E. Then, in this case, it will be impossible for the hot water to be drawn off by the inlet pipe. Many will say that this system is contrary to that generally in use. So it is. But let this be as it may, the system works exceedingly well, and often may be fitted when needs drive. J J is the draw-off pipe from the hot-water tank, which, being continued forward to AIR PIPE and to X, carries off all steam and allows the air to flow from the hot-water tank when it is being filled with water. It should be *properly protected from frost.* I do not like this style of drawing off the water from the tank, but prefer to fix the draw-off pipe about 3in. to 6in. down the tank, as shown at the dotted lines 9, as this prevents the air being drawn down with the water when in use.

HOT WATER is this pipe, branched off the above-mentioned air pipe, and which I object to supply the sink.

In the preceding few chapters I have drawn your attention to the hot-water fitting such as is done by plumbers, &c., generally, and which I will assume that you are, in practice, tolerably well acquainted with; but, if I were to ask you the reason why such apparatus works, the chances are that I should receive an unsatisfactory answer; and to enable you to thoroughly understand this class of work, so as to be able to fit up works of every class, it will be imperative that you should thoroughly master the principles which govern this important branch of your work, so that you may not be, as many of our leading foremen of plumbers are, simply obliged to come and seek information which, I say, every apprentice boy should be able to give before he is out of his time. I may also state that I have, by the plumbing craft, been asked to thoroughly explain the theory of hot water work, together with the practical part, not only suitable for the apprentice boy, but also for the foreman and master.

The Theory of the Circulation of Hot Water Through Pipes, &c.

It will be seen that heat is diffused through water in a very different manner to what it is through solid substances. When the heat applied to the bottom of a boiler or other ves containing water, the first effect is to expand t nearest layer of water to the fire. The fire, reason of its heat, makes this layer of wa specifically lighter than the colder water whi may be by the sides, and especially that abov and these layers being lighter than the co above, it allows the colder water to descen when the hot water naturally rises, or floa upon the molecules of the colder or denser wat which surrounds the hot; then the cold wat from above, by reason of its extra density, imme diately sinks to the bottom of the boiler, when i again becomes heated and again lighter in it turn. These succeeding fresh layers of heate

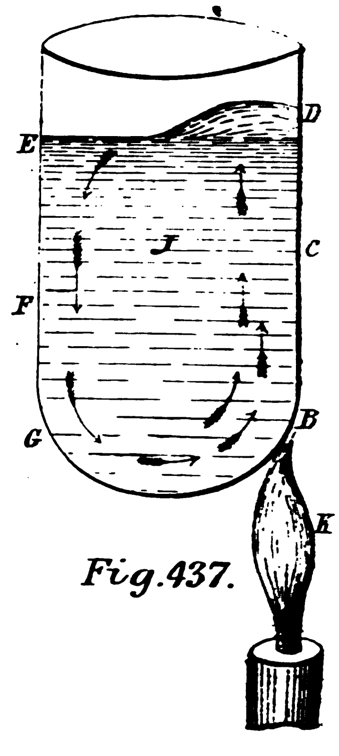


Fig. 437.

water will continually carry the *heat from the* bottom of the boiler to the highest *point of the* circulating tank, which heat, *if the pipes* and tanks be not too large, is finally and gradually diffused through the whole of the water within such pipes and tanks.

For an illustration of this beautiful system, I will ask you to take an ordinary tin can, or, better, an oil flask or other bottle, and nearly fill it with clean water, into which put some bran or other light substance which will not altogether float; then put it over an ordinary gasburner lamp, candle, or other fire, so that you may be able to watch the action of the water. You will see that from the first moment the bran, &c., will be in motion, rising upwards just above the heated part, and, as shown by the arrows B C D, Fig. 437, and downwards at the colder sides, E F G. Place the candle on the other side, and the action will be reversed. Place the candle in the centre of the glass, and the upward motion will be in the centre. Having got so far, next try this experiment with a bent glass siphon, as at Q P W S, Fig. 438, which may be made from an ordinary glass tube, procurable at most chemists, who will also bend it for you, or you may do it yourself, by making it red hot over a fire; or, if you cannot get this, procure a pail or a deep saucepan, and bend a piece of compo. tube to the shape; let the bottom leg go to the bottom of the saucepan, but cut on the splay, so as not to stop the water way, let the short leg just dip an inch or two into the water. Now fill the syphon *quite full* of water, and put the two legs into this water, as shown. Set the pail over a fire, and you will soon find that the siphon will be the hottest, showing that, by reason of the extra length of water in the long leg, the action of the water is more rapid through the siphon than that within the pail, and well establishing the fact that the hot water will travel through any length of pipes as at FLOW and RETURN, Fig. 436.

(*To be continued.*)

PATTERN MAKING.—XXI.

Fluted and Ornamental Columns.

THESE, at first sight, would appear to present insuperable difficulties in the way of moulding. Looking at an architect's drawing, which somehow always does look more elaborate and enigmatical than the actual thing it represents, we wonder how such a complicated mass of ornamental work is to be got out of the mould. The pattern can be made like the drawing; but how to reproduce it in the casting is the difficulty. Drawbacks would perhaps appear feasible on first thoughts; but a little consideration usually reveals practical difficulties in the way of their adoption, and in most cases we are reduced to the method of loose pieces, as being, on the whole, the least troublesome.

We take then a fluted column like that shown in sketch, Fig. 127. Here we have a square base with mouldings, above that a fluted portion, then moulding again; after that a long fluted shaft, surmounted by an ornamental capital. It will be observed that the column in this case varies very much in diameter, being about twice as large in the lower portion as in the upper. The first thing necessary will be to strike out the column to full size, first in longitudinal outline, indicating the thickness of metal by dotted lines, and then in cross sections, Fig. 127, at A A, B B, C C, to show the flutes. To make the pattern, we want a steady foundation—not the actual pattern, but that on which the pattern is to be built. Upon this base the fluted portion will be laid in strips, which strips will be drawn in succession from the sand, after the base is withdrawn. A glance at the section, Fig. 128, will make my meaning clear. Divide the circle into such a number of parts that the flutes will draw readily from the sand; thus, a strip so wide as that shown in Fig. 129, could not possibly be drawn away without tearing down the sand at a a. Let the edges, then, of the extreme flutings be plenty free enough, and do not, for the sake of minimising the number of joints, make the pieces so wide that opposite fluted edges will be *undercut* in relation to each other. There will not be less than six in any circle: eight are better, and in some cases twelve are desi We will have eight in this column. Divid

[illegible] prism was slowly rotated by clock-work [illegible] whether the analyser was whirled round [illegible] times per minute in order to produce [illegible] effects of polarisation.

[illegible] to the binocular instruments there were [illegible] in which not only the tube was as [illegible] halved to form two, but the object-lens itself was actually cut in half. One was so arranged that the two half-tubes and half-lenses would fold together and form a monocular. Here were also the old specimens with parallel tubes, and the modern instruments with their converging tubes. Devices for exhibiting a series of objects arranged on a rotating plate or on a sort of water-wheel had numerous representatives. A gigantic specimen of brass barrel-organ, that once figured at one of the International Exhibitions at the modest price of £300, has found a resting-place in Mr. Crisp's collection. This monster shows some 500 objects, bringing each in turn before the gazer, with its name appended.

For special work, tank microscopes, possessing a power of moving into almost any position and of stretching out to unexpected distances, were met with. For examining the throat and bladder there were instruments specially devised. One long, rod-like microscope, carrying its own electric lamp and a cold water coil to keep the lamp cool, could be passed down the throat into the stomach, so that the progress of such diseases as cancer of the stomach could be watched. Mr. Crisp sought in vain amongst the members for one who would swallow the apparatus in order that the remainder of the guests might survey his interior anatomy. Another microscope clasped the human tongue tightly, so that the circulation of the blood could be seen in that organ. For counting the varying number of corpuscles in the blood of the healthy and diseased, there was ready all the apparatus required. Methods of lighting—oil, gas, and electric—diaphragms, reflectors, condensers, hot stages, electrical stages, live-cells, and all that appertain to microscopy, found there a place. The museum is a very maze of brass. Fabled Argus, could he but stroll in there, might fit himself a tube to each one of his [illegible]00 eyes and then not gaze on empty shelves. A library containing a polyglot assemblage of microscopical literature told of the ancient and modern marvels wrought by the strange forms of brass and glass close by.

In answer to the question: Need the worker of the microscope despair because he cannot command all this wealth of ingenuity? Mr. Crisp replied by taking up a small binocular microscope, costing about [illegible], and remarking "That is what I should work with." The discoveries of science have been made by means of simple and inexpensive apparatus. After inspecting so unique a collection, the question naturally arose: Has the microscope attained perfection? Many hold that it has, and that unless we get some material of higher refractive index than glass, we cannot hope to get much beyond our present power of making visible the unseen. But the same [illegible] finality has been pronounced [illegible] every age of every art. It is true we do not [illegible] in what direction to look for any advance as regards the microscope, but none the less it may be [illegible]. Mr. Crisp's collection shows what has been done and is being done for the perfection of the instrument; it thus warns the inventor of the [illegible] of the past, and concentrates his powers on [illegible] for further improvement.

Amongst the members present were Prof. Grylls [illegible], F.R.S., Mr. W. Saville Kent, [illegible] Dr. Lowne, Dr. Millar, Mr. Pascoe, F.L.S.; [illegible] Rev. Prof. Henslow, Dr. Waller, [illegible] Tubbs, &c.

[illegible] of the Oceans of the World.

[illegible] by Dr. Otto Krummel, of Gottingen, [illegible] of the different seas on our [illegible]. According to his calculations, the Atlantic [illegible] superficies of 10,1[illegible]9,468 square miles, [illegible] Ocean, [illegible] square miles, Pacific [illegible] square miles. Thus the total [illegible] three large oceans is 1[illegible]4,[illegible]87,42[illegible] [illegible] Arctic Ocean has a superficies of [illegible] miles. In the Arctic Ocean, [illegible] superficies of [illegible] square [illegible] square miles, the [illegible] square miles, Mediter[illegible] square miles, Baltic, [illegible] Sea, [illegible] square miles, [illegible] square miles. Then come [illegible] smaller coast seas, viz., [illegible] square miles, Sea of Great [illegible] miles, Sea of St. Laurent, [illegible] China Sea, [illegible] square [illegible] square miles, Sea of [illegible] square miles, Behring Sea, [illegible] Sea of California, 19[illegible] [illegible] superficies of these coastal [illegible] miles. Adding the Antarctic, [illegible] of which is calculated at [illegible] the total superficies of all [illegible] square miles, while the total [illegible] continents and islands of the [illegible] square miles.

SCIENTIFIC NEWS.

◆

THE death is announced of Dr. John Hutton Balfour, Emeritus Professor of Medicine and Botany in Edinburgh University. The deceased, who was a member of many learned societies, was born in 1808, and was for a few years Professor of Botany at Glasgow. His son, Prof. Bayley Balfour, was recently appointed to the chair of Botany at Oxford.

The death is also announced of Prof. Arnold Henry Guyot, the distinguished geographer, who was born at Neuchâtel in September, 1807. Guyot was a student-friend of Agassiz, and after studying glacier and other formations in the Alps for several years during his summer excursions, he emigrated to the United States, and settled at Cambridge, Mass. Guyot was employed as a lecturer in the normal schools by the Massachusetts Board of Education, and by the Smithsonian Institution as organiser of the system of meteorological observations. In 1855 he was appointed Professor of Physical Geography in the College of New Jersey, at Princeton, which post he retained until his death. Perhaps his most important work was the investigation of the erratic boulders of the central Alps in Switzerland and Italy, which he traced over a surface 300 miles long and 200 miles wide.

We have to acknowledge the receipt of the useful "Annuaire de l'Observatoire Royal de Bruxelles," which in its 51st year is full of interesting papers on astronomical subjects, relieved by readable papers on, for instance, the "Most Ancient Towns of Europe," by J. C. Houzeau, the "Rain in Belgium," by A. Lancaster, and the "Tides on the Coasts of Belgium." There are a couple of lithographed plates to illustrate papers on the Transit of Venus, as seen from Texas and Chili.

We have the abstract of the Proceedings at the fourth meeting for the session of the Liverpool Astronomical Society, which, amongst other matters of interest, contains a lithographed plate of Fracastorius and the neighbourhood by Mr. W. Goodacre, director of the Lunar section.

Profs. Anton de Bary, Gegenbauer, L. Kronecker, Virchow, and Wiedemann have been elected foreign members of the Royal Society.

Mr. T. Bolton, of Newhall-street, Birmingham, has issued his tenth "portfolio" of drawings of microscopic animals, and calls attention to the fact that two of the subjects were new to science when he first sent them out. These are Chilomonas spiralis and Asplanchna Ebbesbornii, the latter having been discovered by Mrs. Tupper Carey at Salisbury last August. Raphidiphrys elegans is also believed to be a new find, and Hemidinium nasutum has not been previously figured.

The difference between lard and fat described as tallow is now settled in the United States by the microscopic test discovered or utilised by Dr. W. T. Belfield, of Chicago. Examined as an expert witness in a trial in connection with lard adulterations, he said that pure lard crystals are thin rhomboidal plates, while those of pure tallow have curved forms somewhat like the italic letter *f*.

The United States Bureau of Weights and Measures constructed for the American Society of Microscopists a standard micrometer of platino-iridium (80-20). Prof. W. A. Rogers tested this "standard" during seven months, and it is now kept by the society, who allow it to be used for comparing other micrometers on payment of a fee.

Our correspondent "Devonshire Squire," in sending us a very fine sample of the dried leaves of *Chimonanthus fragrans* (see p. 22 ante, and p. 579, last volume), says that he finds the tea made from them in the usual way has "much the flavour of ordinary green tea; certainly less good than the best, but fully equal to much that is sold under that name. It also seemed (but I may be wrong as to this) to impart a peculiar exhilaration to the nerves." We can corroborate "Devonshire Squire" as to the flavour, which is certainly superior to that of much of the coloured stuff sold as green tea (fine samples of which cost 4s. a pound), but we have not tried the effect on the nerves. There is a peculiar, but not unpleasant, bouquet with the Chimonanthus tea, and it is not impossible that if the leaves were dried by heat like China tea, it would be found as well worth cultivating as an economic plant, as it certainly is as a flowering shrub. It is commonly known as the Japan allspice, and should be in all gardens where it can have the protection of a wall.

M. Wroblewski has, it is reported, succeeded in producing both liquid and solid oxygen in considerable quantity. The liquid boils at −1[illegible], and forms into crystals. Its critical temperature at a pressure of 50 atmospheres is − 113°C.

The parts of a human skeleton found at Tilbury last year, which formed the subject of a paper by Sir R. Owen, read before the Royal Society, have given rise to a lively discussion in certain scientific circles. Sir R. Owen's views are supported by evidence of the close association of the human remains with palæolithic objects found in the neighbourhood; but other authorities are inclined to the belief that the bones belong to a neolithic period. Extensive excavations are being made in the neighbourhood and it is possible that more light may be thrown upon the question.

In a communication to the Academy of Sciences, Paris, MM. Houlès and De Pietra Santa report that they have been unable to discover any injurious action on the health of workmen engaged in working in copper, and they conclude that colique de cuivre does not exist.

LETTERS TO THE EDITOR.

◆

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

A COMMENDABLE MEASURE—THE ARMAGH OBSERVATORY—AN AUTHOR WHO DID WRONG WHEN HE DID WRITE (ON ASTRONOMICAL SUBJECTS)—SUNRISE ON THE CLUN STONE CIRCLE—LUNAR CYCLES, &c.—MEASUREMENT OF THE POWER OF A TELESCOPE—NAKED-EYE OBSERVATIONS OF THE HEAVENS—LEGAL—THE CRESCENT MOON.

[23331.]—I SEE that it is stated in the newspapers that "the International Institute for Preserving and Perfecting Weights and Measures will soon send five scientific gentlemen, elaborately equipped, including one Englishman and one Frenchman, to remeasure the Pyramid of Ghizeh, and especially to uncover and examine the foundations of it, and of the Sphinx, with a view to settle finally differences between reports of earlier observers, and particularly to supply material for re-enforcing the established weights and measures against the progress of the metric system." Beyond the fact that the Institute is an American one—or, at all events, has its head-quarters in the United States—I know nothing about it, and shall be glad to hear from any of my brother correspondents on the other side of the Atlantic, something as to the amount of deference to be paid to its decisions. Should it turn out that they carry weight and authority, I can hardly fancy a more interesting or important work than that which the Institute has imposed upon itself. To get, once for all, accurate measures of Pyramidal details, made by men who have no theory to support, would be, I fancy, to give a coup-de-grace to the innumerable crazes concerning its quasi-supernatural origin, which have been, and are, from time to time paraded. As for the effort to stem the progress of the metric system, it will have the heartiest sympathy of every one in this country who is unconnected with South Kensington. That the British yard and inch should ever be superseded as units of measurement by subdivisions of an erroneously determined quadrant of a merely local meridian, would be as discreditable to Englishmen as it would be ridiculous and unnecessary. Somehow, though, I fancy that measures which have been in use in this

Maclean spectroscope, which does not seem to have been seen in that position by other observers.

The night of Feb. 2 was a good instance of the lightness of nights to which I drew attention on p. 333. Through the evening, while the crescent moon was up and after she set, it was as dark as usual, but when I went out to the observatory again at 1h. there was a great contrast. Everything in the observatory was quite plainly to be seen, and I could comfortably move about and get things; in fact, I could almost have written my notes, for the book was plain, though I could not have seen the pencil marks. Out of doors, buildings, trees, plants, and the gravel walks, both near and at a distance were quite distinct. But the definite test of the amount of light is that at ten minutes to two, standing up at the open shutter, I could read the time by my watch. It has a white face, and is 1¾in. in diameter. The only guide I had to the time was that I knew it was some time after half-past one. The light was colourless, and exactly like the first beginning of dawn on a fine starlight night. The sky looked whiter than usual, but there was no perceptible mist. The stars were brilliant, and faint ones were well seen in numbers, though the sky was not as crowded with them as sometimes. The definition of Jupiter and Mars was good, and they were very brilliant. The lightness lasted at least until 3 a.m., then I came in, and when I went out again for further comet-seeking, at 5 a.m., it was as dark as usual. The night was dry and calm, without a cloud. The thermometer went down to 28° at 1h., and still further to 25° at 5h. 20m. It was the first frost we have had for some time, and we have not had another since. The light of the dawn at 6h. 30m. seemed to me equivalent to the amount of the other light. It was the first night clear throughout that we have had for some time. **M. A.**

STAR MAGNITUDES.

[23333.]—In his estimates of the brightness of comet Pons-Brooks (letter 22313), Mr. Hennessay says that his estimates of the comparison stars differed in some cases from those given by Heis. The following magnitudes, found by Professor Pritchard with the "wedge" photometer, will show that Mr. Hennessay's estimates of relative brightness were quite correct:—

γ Pegasi	2.47	Heis 3-2.
α Andromedæ	2·05	Heis 2.
τ Cygni	3·68	Both 4m. Heis
κ Cygni	4·23	

I have compared the magnitudes given by Mr. Gemmill (letter 22312) with Professor Pritchard's results, and find a generally fair accordance. The following are the most remarkable discrepancies—recollecting that Professor Pritchard's standard is Polaris = 2·05, and Mr. Gemmill's Polaris = 2·2:—

	Gemmill.	Pritchard.	
α Ophiuchi	2·0	2·23	3m. Sufi, 3m. Houzeau.
ν Cygni	4·0	4·23	
ζ Cephei	4·2	4·32	
κ Cephei	4·3	4·50	5—4 Sufi, 4·8 in *Durchmusterung*.

With reference to the magnitudes he quotes from Heis and Argelander, I find the following discrepancies (the scale of Heis and Argelander being the same as that of Pritchard):—

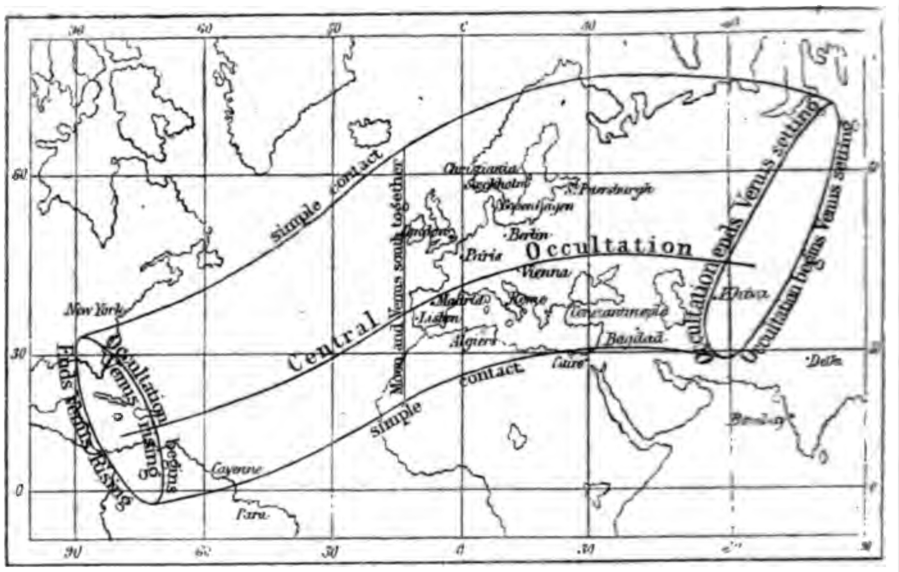
	Gemmill.	Pritchard.	
α Cygni	1·7	1·35	This in Gemmill's scale would be 1·50.
Castor	1·7	1·48	
β Herculis	2·3	2·67	Suspected variable.
ζ Leonis	3·0	3·39	
ν Ursæ Maj	3·3	3·50	
λ Orionis	3·3	3·52	Suspected variable, Gould.
χ' Orionis	4·7	5·10	5·4 in *Durchmusterung*.

I should add that Prof. Pritchard's results are "zenithal magnitudes."

9th Feb. **J. E. Gore.**

OCCULTATION OF VENUS.

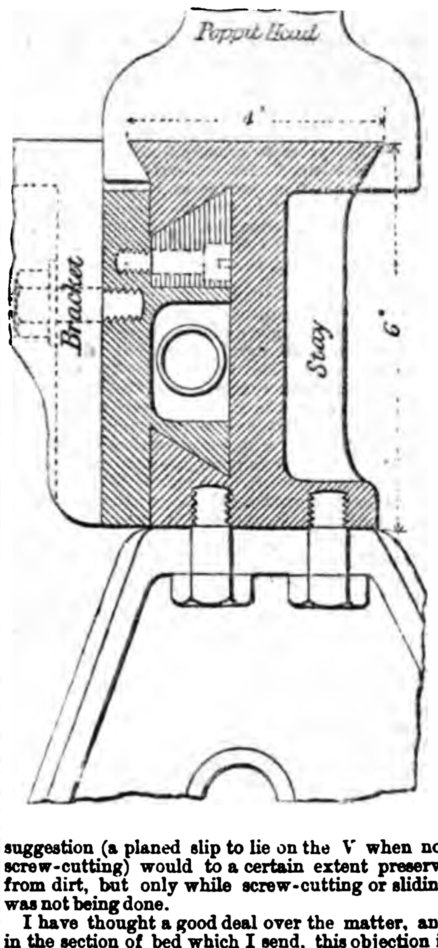
[23334.]—Venus will be occulted by the Moon on the 29th inst. As the phenomenon will be visible in the whole of Europe, the annexed chart, taken from *l'Astronomie* will, perhaps, interest our astronomical readers. It has been worked out graphically by Mr. E. Blot, of Clermont (Oise), and shows by simple inspection in what places the phenomenon will be visible. At Paris the occultation will last from about 3h. 13m. to about 4h. 33m. p.m. The phenomenon will easily be *seen with a telescope*. The planet will disappear at about 55° east of the Moon's north pole, and reappear at about 100° west. **C. Detaille.**



THE FRONT SLIDE LATHE.

[23335.]—Mr. Bear's statements as to the action of the front slide are most valuable, coming from one of such experience. One hundred years' wear, I think, ought to satisfy most of us. So we may regard the question of abiding accuracy as settled.

We may pass by the objection of general appearance, as hardly worthy of being set against convenience. The V slot being a receptacle for chips and turnings, and also being oily, as the Britannia Co., in a private letter to me on the subject have pointed out, is a thing to be considered. Their suggestion (a planed slip to lie on the V when not screw-cutting) would to a certain extent preserve from dirt, but only while screw-cutting or sliding was not being done.



I have thought a good deal over the matter, and in the section of bed which I send, this objection is in a great measure got over, and the construction of the bed much simplified; while there are several other advantages gained, without (as far as I see at present) any serious disadvantages.

It will be seen that what I suggest is a modification of the ⌶ form of bed, which Major Armstrong proposed as suitable for his combination lathe, and which, in a rough calculation he made for me at the time, he showed to be stronger and stiffer than the ordinary double bed, supposing the same weight of metal to be in both beds.

His calculation for the breaking weight of a double bed 4¾in. gap by 5½in. wide, is 52·30; for an ⌶ bed same weight breaking strain is 61·87; while the cross resistance in the two cases would be 5·06 and 9·18, thus giving on the two counts a gain of more than 50 p.c. in favour of the single flange.

I don't think my illustration needs any explanation. The mandrel head, after Major A.'s plan, would be cast solid with the bed. The poppet fixed by his method. Several stays would be put in at back, and this bed could very easily be made with a gap.

The bracket for rest, which I have only shown in part, could be made to slide vertically on the saddle either by screw or hand, and would be fastened when at proper height by two bolts. This would be convenient for many purposes. The rest might also be made to slide forward on to top of bed, between V slots on top of bracket, and be held by a bolt as suggested by "O. V." in his first letter.

I submit this design to Mr. Bear and "O.V.," as at least solving the oil and chip difficulty, and also securing the V edges from all possibility of injury from chance knocks.

I do not know whether these modifications of Major Armstrong's design are covered by his patent; but as the Britannia Co. were, I believe, intrusted with the carrying out of his complete design, they could easily arrange with him about the adoption of any portion. At any rate, it seems it is to Colchester that amateurs must look for any help in carrying out this design.

I presume Major A. is still in India, else he might help us with his opinion and suggestions, for I cannot but think the man who designed his combination lathe is, after "J. K. P.," the one most fertile in resources suitable to amateur wants.

We will, however, anxiously look for the screwing attachment referred to by Mr. Bear, and which he thinks will be much better than the front slide lathe for most amateurs. But if I understand him rightly, the whole saddle with slide rest attached hinges over to the back, so that poppet has to be unshipped twice for each time you use the hand rest. But I suppose the cost of the arrangement will be much much less than a regular screw with saddle and set of change wheels; and with many a one that means the putting a self-acting screw cutter within his reach. **Fredk. Carre.**

MICROSCOPIC TEST OBJECTS.

[23336.]—"Monachus," in his letter (22261) has evidently misunderstood me regarding "true structure." I was not alluding to the ultimate true structure, but was speaking only of the marks that were under discussion, with which we are all acquainted, and whose diffraction spectra of the first order are taken up by even moderate apertures. I still adhere to my statement about the S. gemma. The markings on my best specimen counted transversely 55,000, and longitudinally 68,000 to the inch. The diffraction spectra of the first order from these markings would make angles in air of about 70° and 90° with the dioptric beam respectively. A $\frac{1}{12}$th, N.A., 1·43 therefore, would amply admit, with axial illumination, these—viz., the dioptric beam and one diffraction spectrum of the first order on either side of it.

If the finest lenses of the present day are unable to show the true markings (not ultimate structure) of the P. formosum, P. angulatum, and S.

methylated spirit of 82 p.c. by volume to obtain 80 p.c. by volume? Answer $\frac{50}{82}$ There must be 50 parts of spirit in 82 of the mixture, or nearly 2½ to every 2 of water. Similarly, how much water to rectified spirit of 89, to obtain 60. Answer $\frac{60}{89}$; and 89 – 60 = 29. Close upon half as much water must be added. So of 75 p.c. and other percentages.

Chromic acid, often contaminated with sulphuric acid, ought to be in the form of dry red crystalline needles. In buying it, ask that it be perfectly dry, since moisture will make it weigh heavier than it ought to do, and will thus falsify the solutions. It ought to be kept in a closely-stoppered bottle; and perhaps it is the best plan to make a strong solution of it (say 25 p.c.) at once, so as to eliminate the difficulties occurring from its vehement tendency to "deliquesce," or dissolve in the water contained in air. *Bichromate of potash* (red chromate) has properties similar to, but feebler than, those of the free acid; as also has *bichromate of ammonia*, a salt of similar appearance, which may be made by neutralising chromic acid with ammonia. Bichromate of potash hardens very slowly, but is not so apt to produce granulation as chromic acid itself (alcohol possesses the unpleasant property of producing granulation in a pre-eminent degree). Solutions of bichromate of potash have to be four or six times as strong as of chromic acid. Bichromate of ammonia acts more vigorously than the other bichromate, and has been used microscopically for brains and spinal chords; it seems to be the salt recommended by Klein as showing a fibrous network in protoplasm, especially in that of large glandular animal cells. Klein employed a 5 p.c. solution for 24 hours; then tinged with picrocarmine; and mounted in glycerine. The appearances he observed are regarded by Fleming and others as *post mortem* phenomena.

The question continually occurs, "Shall I have to use distilled water, or will good common water do?" For solutions or dilutions of the above substances, and for all ordinarily microscopical purposes, good ordinary water suffices (I find the London water gives but little trouble, except with salts of silver and of lead); but for recipes of mounting liquids, distilled water (which is very cheap) is doubtless preferable. Even the distilled water is not pure, and it will be well to see that it is free from films and sediments, or, if they are present and no better water can be had, to filter them away. Of other water, clean rain water is the best; and all water except good distilled water ought to be well boiled, allowed to stand for a few days in a full bottle, to deposit any sediment which may fall from it, and the clear supernatant fluid drained off or filtered. This boiled water also helps to take the air out of tissues. Besides its power as an ordinary solvent, water dissolves the thick syrupy substances among the tissues, and thus causes their more solid parts to stand out more boldly. It also dissolves tissue cement, or disintegrates it, though slowly; and in the first instance coagulates protoplasm, which afterwards disappears, or becomes indistinct. Hence the details of a transverse soft-stem section look more distinct after an hour or two, but finally become blurred and unintelligible. Of its power of swelling and bursting cells, mention has already been made.

II. *The Process of Hardening.*—In hardening, the first thing is to make sure that the object is thoroughly penetrated by the hardening agent. The fresh object, therefore, has to be cut into pieces of not more than half an inch, or so, in their greatest thickness, the precise size depending on the hardness and density of their tissue, since, otherwise, the interior may remain soft, or even putrefy. Alcohol penetrates more rapidly than chrome solutions; it also possesses greater preserving power, so that with chrome solutions the pieces must be cut smaller. Air will also prevent the entrance of hardening agents, and alcohol removes it better than watery fluids (though they also do this, especially if the water has been boiled), so that stems, &c., may be slit down before immersion. The next thing to provide against is, that the action, though finally complete, shall not be too violent. If this is not attended to, the exterior of the object, by the greater firmness communicated to it, may prevent the deeper penetration of the fluid; and besides, a hardened object is really a *remarkably firm clot*. The albuminous matters are coagulated and contracted, while with alcohol they are contracted by the removal of their water as well; and if this clotting is violent, they preserve nothing of their natural form, but the object is seen, when examined microscopically, to present little more than a multitude of granules or clots, giving it a mottled appearance in which almost every trace of the original structure is lost. The proper precaution against these dangers is to increase the strength of the fluid gradually, so that the slight coagulation effected by the first and weakest dilution, while too inconsiderable to give rise to any appreciable *denaturalisation, may com*municate a solidity sufficient to protect against distortion by the next, and so on till the hardening is completed. Consequently a beginning is made with spirit containing 45 p.c. or less alcohol, if alcohol is the agent employed, while with chromic acid, although the solution *may* be as strong as ·2 p.c. with coarse and stable tissues, it may be as weak as ·02 p.c., especially where it is desired to clear up contained tissue elements. After this has had time to penetrate thoroughly—say, in a couple of days, the length of time required will depend on the size of the pieces and the permeability of the tissue—the solution has to be changed for another nearly twice as strong for chromic acid, or with alcohol, containing about half as much water (75 p.c. alcohol for three days or so). This changing has to be repeated till the objects lie in pure methylated or rectified spirit, or, if obstinate, in even stronger alcoholic fluid; and, with chromic acid, till a strength of ·5 or 1 p.c. has been reached. In this they may have to remain for weeks before the requisite hardness is attained. They should at last feel like fresh radish, and may be taken out from time to time to see how hard they are, while part may be left in longer, to see how hard it will become. Over-hardened objects are thready, brittle, pulverulent internally, or notably shrunken. As a rule, objects which stain more rapidly also harden more rapidly.

Spirit is preferred for glands, the digestive organs, "lymphoid" tissues, and morbid growths, which decompose with extreme rapidity. It also penetrates vegetable tissues and expels their air, as has been said; but small delicate vegetable objects harden well in chromic acid, and so do soft roots. Objects, moreover, often harden better when two different agents are employed than when the whole of the process is trusted to one only; so that spirit is often used to complete hardening commenced by chrome solutions. It is also recommended to begin with bichromate of potash, and follow it up by chromic acid, which is more powerful, and less easily managed as to the precise strength to be employed. Chromic acid is preferred to spirit for nervous tissues and organs of sense, and also where the object is partly composed of bone, as in the internal ear. It both hardens the more delicate tissues, and softens the bone by decalcifying it, so that on account of the more uniform texture thus produced, sections are more easily cut. Chromic acid and other chrome solutions have the disadvantage that they communicate to objects unpleasant tints which interfere with the subsequent staining, though less so where hæmatoxylin is employed. If used too strong, practically irremovable deposits are also left in the tissues. The colour is removed or diminished by washing or steeping in spirit, especially if a little acetic acid is added. Both alcohol and chrome solutions render objects more opaque from coagulation, the latter also by colouring, or, additionally, by the deposits just mentioned. If the objects are to be mounted resinously, the processes employed will doubtless sufficiently clear them; if not, steeping in glycerine and acetic acid will do so.

The following points deserve notice:—(1) Spirit or chromic acid which has been already used for hardening, and, consequently already contains a certain amount of albuminous matter, acts less harshly than what is raw, and may be first used. (2) The fluid used ought to be of six or eight times *the bulk* of the objects, or its power is exhausted in a few hours; time is wasted, and putrefaction invited. More of a weak fluid acts like less of a strong one, except that the latter first works energetically, and then does nothing. (3) To insure gradual action, the objects may be wrapped in moist cotton wool (recommended by Cole with chromic acid); glycerine may be added, or, as recommended by Beale, the chromic acid solution may be made with glycerine instead of water. In this case the object must be cut very small, on account of the low penetrating power of glycerine. (4.) To guard against incipient decomposition, a little spirit, chloroform, or both—a quarter, or more, of the former, or ·5 per cent. of the latter, may be added to chrome solutions. For the same reason, all hardening objects must be kept well corked or stoppered up. (5) In decalcifying, more than 1 per cent. chromic acid may be employed; but much more may be risky, inducing brittleness, especially in fresh objects. Its action, however, may be eked out by adding a few drops of nitric or hydrochloric acid to the ounce of solution, or, what comes to the same thing, a 2, or even 3 or 4 per cent. acid may be shielded by being dissolved in glycerine, which will also give it a longer time to act in, by protecting against decomposition. The requisite quantity of the strong 25 per cent. solution may be mixed with glycerine. (6) A solution which is notably turbid, or has become highly coloured, should be changed. Its strength is being consumed on matters drawn out of the object. And finally (7) hardened objects need not be used at once, but may be transferred to 45, or so, per cent. alcohol till wanted.

III. *Wet Mounting.*—The general features of this process are the same as those previously described for resinous mounting. The following are the special points to be attended to:—

Firstly, steep the object for some time in the fluid in which it is to be mounted. For this there are two reasons, besides that mentioned above: First, where glycerine is used, the stronger the glycerine is, the better, of course, it preserves, while the objects move less in denser fluid (if they are not rendered immovable by being pressed between the slip below and the cover above), and are thus less liable to be damaged. If, however, delicate objects are put at once into strong glycerine, they simply collapse; but if transferred gradually from weaker (20 p.c. or so) to stronger solutions, they recover themselves after each bout of contraction. The rationale is here the same as that of gradually strengthening hardening fluids; indeed, a little of a hardening agent may usefully be added. Another advantage of steeping in glycerine is that it often *uncurls*. For instance, exceedingly thin wood sections may be cut as Sachs recommends, by hardening in spirit and allowing to dry, or with a section cutter, by moistening the wood and the razor with glycerine and as much spirit as suffices to make this run. A thin wood section almost inevitably coils up into a minute roll, if it is horizontal or transverse; but by steeping in glycerine it flattens again at least sufficiently to be flattened further by gentle handling with two small camel-hair pencils. The first reason for steeping, then, is to avoid subsequent collapse; the second is that the object may render the mounting liquid opaque from the precipitation of small particles contained in its juices. If this happens after mounting, the slide is, of course spoilt; if it is allowed to take place before, the fluid must be repeatedly changed till it occurs no longer and the object clears again. It need scarcely be said that, independently of opacity occurring in this way, the object itself may be opaque, from its nature or the thickness of the section. This may often be remedied (with bleaching, it is advisable to remove colouring matter) by introducing caustic soda or acetic acid into the preparatory steeping fluid; but soda must be carefully and entirely removed before mounting. The complete removal of acetic acid is not of so much importance; but if either of these reagents has been employed, their specific effects (which have been already described) on the tissues must be allowed for, and the specimens must not be compared with others in which they have not been applied without their results having been discounted. But thick sections are best treated by Canada balsam mounting, which clears them better than glycerine or Canada balsam and chloroform, or benzol, and much better than the thin fluids also used in wet mounting. At the same time, a thick section is not objectionable chiefly *on account of* its opacity; that, as we have seen, can *be removed*, if it is not scandalously and unbearably *thick*, as the first sections are likely to be. The principal objection to it is that it is confusing, and does not show the details, being layer over layer. *Secondly*, having sufficiently steeped the objects, put a thin layer of gold size or Bell's cement on the cells which are to receive them. Have some cells, then, prepared as described in the first of these letters, but dry and hard, not waxy, so that they will not injuriously give or change shape after the covering glass is applied. It is well to have a number of cells ready, of different sizes and depths, as they may be wanted on occasion; and one of greater depth or dimensions than is necessary to contain the object with a due amount of clear space round it ought not to be used. For the object might then swim loosely about in the interior of the cell after mounting, be difficult to focus, and liable to injure itself in its movements, or to escape out of sight; and again, small cells hold better than large ones. The reason why shallow cells are longer lived than deep, and cells of small than those of large diameter, is that the suction of the contained liquid when it contracts with the cold of winter, and its outward pressure as it swells with the summer's heat, are smaller in comparison with the resisting power of the cement inclosing it. Hence, large cells burst or admit air-bubbles by contraction, while lesser ones, or those more thickly coated with cement, remain firm; and so, also, gold-size cells are more likely to hold than vulcanite rings, and vulcanite rings than glass cells, which accommodate themselves least to variations of temperature and pressure; metal cells hold well. For the same reason, all variations of temperature (those of atmospheric pressure cannot be avoided) are bad for a microscopical cabinet, which is, therefore, best kept where it is never very hot and never very cold. Besides, a cabinet ought not to be made of cedar wood, or any wood containing turpentinous matter. The reason why the top of the cell should be covered with a thin layer of cement is that the cover, when applied, may be capable of being worked down a little way into it, forming a kind of shoulder-joint, so as to effect a more perfect juncture. To make the top of the cell of the same level all round, it may be gently pressed with another slip, moistened with water or glycerine, to prevent accidental adhesion; and a way out for but Cui bono? The mere statement of the tractive force cannot be of much use, unless something is known as to the rate at which the engine can move while exerting it; and directly this element is introduced, the conception of horse-power becomes applicable to the work. An engine with a traction of 9,000lb. would be no use, practically, if she could, by reason of short supply of steam, only exert that force at the rate of a mile an hour. I wonder "Historian" does not see that his determination of tractive force is of little value until has been found (by experiment I suppose) the speed at which the engine can run. So far from horse-power being an unpractical form, it is much more practical than tractive force. I gave an equation some time ago, in which the speed of an engine with a given load, on a known gradient, was determined from the horse-power and train resistance, and it would not be possible to make any similar determination from tractive force only. I hope, in future, that correspondents will do what "Historian" and I alike agree would be useful, i.e., send statements as to the actual performance of engines of given dimensions: this would greatly enhance the value of the replies, many of which are now of a very trivial nature. No one admires more than I do the magnificent pieces of mechanism, which we owe primarily to the genius of the Wylam mechanic; but I confess to not feeling much interested in learning that No. 843 has been painted green. On page 429, I stated that I wished to have the opinion of Mr. Stretton as to the accuracy of the calculation on page 386. He seems to have overlooked this request, and I desire to draw his attention thereto. The dimensions were given by him, and I want him to check the work.

Elswick Science School. **Wm. John Grey.**

G.E.R. GOODS ENGINES.

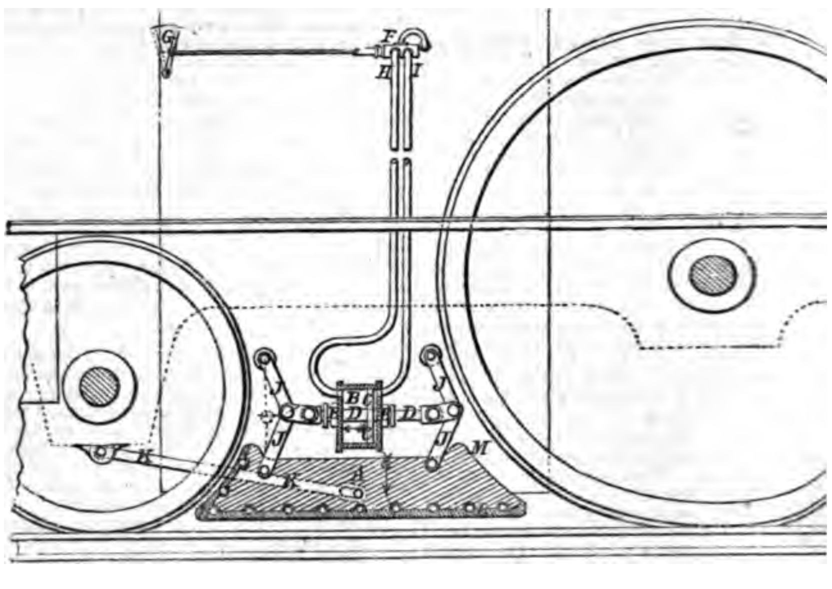
[23345.]—The following are chief dimensions of the fast goods engines, designed by Mr. Adams, and illustrated in my letter 21581, p. 411, of last volume:—

	ft.	in.
Cylinders	18in. by 26in.	
Inclination	1 in 18in.	
Diameter of driving wheels	6	1
" bogie "	3	1
Bogie centres (apart)	6	0
Rear bogie centre to driving wheel centre	8	6
Driving wheel centre to trailing wheel centre	8	6
Total wheel base	23	0
Boiler centre to level of rail	7	0½
Length of frames	28	3

The boiler barrel is 11ft. 6in. in length, and the firebox 6ft. The connecting-rods are of the same length as those on the large single bogie express engines, 245 class, the distance between centres being 7ft. 6in.

I can, if desired, send a further sketch of these goods engines, since the first was defective, which will serve to correct, and to show to better advantage, their very fair dimensions and powerful appearance. **F. W. Brewer.**

M'CONNEL'S STEAM SLEDGE BRAKE.



[23346.]—Attention has recently been directed to "sledge brakes." I therefore send a diagram and details of McConnel's system, which was patented 26th February, 1857 (No. 591.)—It consisted of two sledges (A) usually 4ft. 6in. in length, and 4in. wide, one fitted to each side of the engine between the driving and trailing wheels; a steam cylinder (B) 9in. diameter was also placed horizontally as shown on the drawing. Each cylinder contained one piston (C) fixed to a rod (D) which passed through both ends, stuffing boxes (E) were therefore provided upon both covers. Steam from the boiler passed to the slide-valve F, and by means of the handle G, the driver could admit it to either pipe (H or I), and consequently to either end of the cylinder (B), or he could close all communication.

The action of the brake was as follows:—When steam was admitted to the front end of the cylinder by the pipe (I), it caused the toggle joints (J) to straighten, or partially straighten, and this had the effect of pressing down the sledge (A) on to the rails, whilst the radius rod (K) served to draw it simultaneously against the tires of the trailing wheels. By admitting steam to the opposite side of the piston, the contrary effect was produced, and the sledges lifted up and the brake taken off.

The sledges were faced with wrought iron or other suitable material, the face (L) being bolted on as shown.

It should be pointed out that the leading end of the sledge (M) did not even touch the driving-wheels, but it is shaped so that in case of accident these wheels could not possibly mount it.

Several modifications were made by Mr. McConnell: in one, the cylinder was placed vertically instead of horizontally, and other forms of slide-valves and taps were tried. It was proposed to extend this brake throughout the length of a train; but experiments made at Wolverton with a few lengths of iron pipe proved at once that the condensation of steam would render the brake useless if applied to carriages; it therefore remained as an engine brake only.

Colonel Yolland conducted a series of experiments with McConnell's brake, 19th January, 1858, upon the Bletchley and Oxford branch of the London and North Western Railway.

	Tons.	Cwt.
Weight of engine	29	0
Weight of tender	14	10
Weight of carriages	102	9
Weight of vans	10	4¾

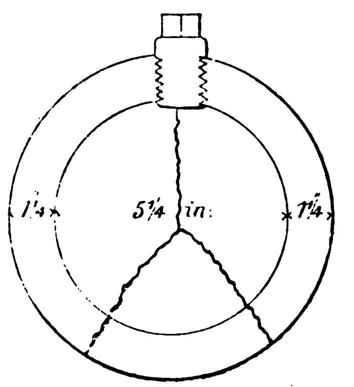
Eighteen experiments were made with the steam and hand brakes; but although the steam sledges gave a comparatively high retardation in lb. per ton of weight resting upon them, yet it was soon found that in practice all the forms of sledge brakes were inefficient and inferior to the ordinary brake-blocks pressed against the tires.

Clement E. Stretton.

Saxe-Coburg-street, Leicester, Jan. 30.

ICE-FRACTURED SHELL.

[23347.]—In conducting, the other day, one of Professor Tyndall's interesting experiments illustrating the enormous and rapid expansion of frozen water, I used a 7¾in. bombshell, whose cavity held 45 fluid ounces, the thickness of the iron being 1¼in. I placed this shell (filled with water at ordinary temperature, the orifice firmly closed with an iron-screwed plug) into a mixture of snow and salt. In 78 minutes I found the bomb broken into three pieces; the same day I burst other two shells. Two queries presented themselves: *Why* should the line of fracture in all three cases be the same, and in the case of the 7¾ shell, what pound-pressure principle had been exerted, its internal cavity being 5¼in.? Position of shell in mixture as shown in sketch. **T. R. Clapham.**



GLASS DISCS FOR REFLECTORS.

[23348.]—I think we are much indebted to Mr. Wassell and Mr. Scott for their valuable experiences. Mr. Wassell's rules as to proportion of diameter to thickness and strength, will be duly appreciated. Mr. Scott relates facts and tries to account for them; but I am not certain that I have made it clear to him all I meant by "even texture"—that depends in a great measure on the flow of the molten glass, as well as on the annealing. My gl apparently poured out on a flat surface in *sheet*, and left undisturbed to cool as slo could be done. The grain or texture, as i would therefore be in an *even*, straight line, glass cast in moulds will have to flow in al tions, *wave over wave*, probably *radially*, an not see the possibility of cooling the centre circumference quite evenly. Mr. Wassell's of cutting the disc is rather primitive and t just what I wished to avoid. I feel somewh prised that the many practical glass worker neighbourhood could not, or would not, sug him simpler ones; but I hope we shall receive more information yet on this point. A ready of cutting thick glass into discs would be accep to builders, plumbers, and many others, b amateur mirror grinders; it may, therefor worth ventilating the subject. I had an id trying the following method, unless some who has already tried it will kindly warn me

Having cut the sheet of glass into strips will successively be placed on the wheel, an a good diamond have a clear circular cut t of the intended disc made into them. S transverse cuts outside this will divide the Now a white-hot iron ring will be dropped ju side the marked circle, and, if need be, a d ice inside it, striking sharply the edges at time. I have succeeded this way with glass thick, and hope to succeed with thicker sect have never seen explained how it happens t scarcely visible mark from a diamond or other pointed substance should cause a piece of glas thick to part in two under it. Can crystals b in the same way? Will these cuts not reveal something about the constitution and concate of the molecules? **A. Capla**

[23349.]—A good plan of cutting these wo to have copper cylinders made to size of required. The cylinder should be fixed to a or some machine which would give it a ci motion. Place the glass underneath with cyl on top; set it in motion, and feed with emery water. There will be no risk of breaking, an edges will be left in first-rate condition. The need not be cut into squares first.

W. Pot

PHOTOGRAPHIC SCREW-THREA

[23350.]—One more step has been taken t the methodising and simplifying our English threads. The Photographic Society has a certain standard screws for photographic app and henceforth, photographic lenses will changeable among various cameras, and a source of complexity, annoyance, and expen be eliminated. In order to maintain unifo and give photographers an opportunity of ing their screw tools, Sir Joseph Whitwor Co. have, at the request of the council Society, manufactured a beautiful series gauges, which will be kept at the office Society as reference standards. The fol particulars of these gauges will be of inte your readers.

As to thread-form, that of the Whi standard screws has been adopted—i.e., an is triangle of 55° with one-sixth rounded off and another sixth rounded off at bottom of circles touching the sides of the triangles.

As to thread-rate, the special character light brass tubular fittings of the cells and of large lenses renders the engineer rates able, and the following thread-rates have been adopted:—

For 5in., 4in., and 3½in. diameters, 12 threads per inch.

For 3in., 2½in., 2in., and 1½in. diameters, 24 threads per inch.

For stop and accessory screws, four sizes are adopted, 3/16, ¼, 5/16, ⅜in., with thread-rates of 20, 18, and 16 per inch.

The above diameters are in all cases measured to the outside of the perfected thread.

The gauges all carry cylindrical portions giving the diameters to the inside of the perfected thread, and therefore show the extreme sizes to which the internal screws should be bored out before threading.

The gauges are in steel, not hardened, with the centres upon which they were manufactured left intact. They are as follows:—

One large three-step gauge (12 threads per inch) for the three largest screws. Each step gives, 1st, a cylindrical portion which should just slide inside the perfected thread of the internal screw; 2nd, a threaded portion upon which the internal thread should screw solidly up.

One large four-step gauge (24 threads per inch) for the four next screw sizes. Each step gives a cylindrical and threaded portion, as in the larger gauge.

Four small internal gauges for the stop and accessory screws. Each of these gauges has two cylindrical portions giving diameters for inside and outside of thread, and a threaded portion for gauging the perfected screw (16, 18, and 20 threads per inch).

A steel gauge plate, having twelve holes in four ets of three each. The three holes give for each size of these stop screws diameters for top and bottom of thread, as well as gauge for threaded screw.

With the above gauges there is also a tray of seven standard screwing tools, in hardened steel, for originating the 12, 16, 18, 20, and 24 outside threads, and the 12 and 24 internal threads. The whole apparatus is fitted into a mahogany box.

We have heard no more of late as to the progress of the steps being taken by the council of the Amateur Mechanical Society for adopting intelligible and properly defined lathe threads for the use of their members. If ornamental turning is to progress as a scientific amusement, the present complicated and absurd conglomération of screwing tools must be superseded. The Royal Microscopical Society has for a whole generation had the advantage of a standard screw for its objectives; why should the members of the Amateur Mechanical Society not have a standard mandrel-nose for their lathes? Who stops the way? **H. O. M.**

PUMPING BY SUCTION.

[23351.]—I am not quite so sceptical as "D. L." (22303) regarding this paragraph, and should be glad to have P. J. Davies' attention called to it, and let him give us his views upon the matter. I am not one of those who are so ignorant as not to know it is the pressure of the atmosphere that raises the water from the well; but "there are more things in heaven and earth than are dreamt of in our philosophy." **H. C. B.**

[23352.]—Dr. Atkinson *would* certainly have to "bring out a new edition" if he wished to prove the existence of "suction" as a factor in the working of the common pump, for it is plain that the present one does not attempt that feat.

Paragraph 206 (10th edition) shows plainly that Ganot, in common with Deschanel (pp. 211 and 213), uses the term technically, for we have—"The air being thus rarefied, water rises in the pipe until the pressure of the liquid column, together with the tension of the rarefied air which remains in the tube, counterbalances the pressure of the atmosphere on the water of the reservoir."

I suppose "the piece of wood, &c.," requires to be adjusted so as to preserve this rarefication, and certainly not for "suction." There are not "two sides" to the question at all. **Egstow.**

INGROWING TOENAILS — ELECTRIC BELLS—MEDICAL COIL.

[23353.]—Ingrowing (or inverted) toenail may be cured by mechanical means if not too far gone. The object is to raise the corner of the nail out of and over the flesh into which it is growing; this can usually be done by inserting (with the blunt end of a darning needle) a small piece of lint, putting a fresh one in each day, and gradually increasing the size of the plug. I had one cured in this manner by an eminent surgeon, and I have since successfully treated several others.

On page 478, a correspondent indulges in a long grumble at one of my replies (and in an almost equally lengthy signature). Several others have answered the query (57277); but they have not given exactly what was required. "Practice" gives a contrivance to ring the bell while the door is opened, and then to stop. The reply of "Cosmos" leads to the same end.

"Chemicus" asked for a contrivance which should ring for a *certain time* after the door was opened, whether door should remain open or closed, and I doubt whether the 2s. apparatus (which is *not* described by the gentleman with the long signature) is capable of measuring or indicating any time whatever, and I don't find the required contrivance in any list which I have. That is all I have to say about it.

A very good medical coil can be made on a bobbin about 3in. by 1¼in. For the core ¼in. iron rod, brass tube for regulator, three layers No. 26 silk-covered wire, and 12 layers No. 36 for secondary. Wind and connect the primary as usual; but join the secondary to it, and take the shock through both wires. A bichromate cell, with about 2 square inches of zinc, will give more power than "J. E. A." can possibly require. **Os.**

[23354.]—Whatever else "One Who Suffers" may do, do also this: bathe the foot in water comfortably warm, to soften the nail and the flesh also; then wipe very dry, and at once insert a thread of fine worsted under the corner of the nail, drawing the thread as far in upon the "quick" as can be done without causing very much pain—there must be a little, but it will lessen daily—cut off the ends to within ½in. of the toe, lest the worsted should get dragged away, and draw it more and more under nail as it grows away from the flesh. This is a speedy and most effectual cure. **H. O'B.**

BREAD ADULTERATION — COPPER SULPHO-CYANIDE — EXTRACTING ALCOHOL FROM OIL.

[23355.]—"Bread adulteration" by potatoes (query 52679, p. 416) would have to be very considerable to be objectionable. In my opinion, the use of a moderate proportion of potatoes in bread-making is just as legitimate an addition as that of salt, yeast, or water. A very large proportion of potatoes might be regarded as a true adulteration, but probably such an addition would prevent the rising, owing to the deficiency of potatoes in gluten. The detection of potatoes is best effected by the microscope, but is very difficult, owing to the change produced in the starch-corpuscles by the heating to which they have been subjected; 40 per cent. of water in bread is not an excessive proportion. I am not aware that any salts are used in weighting bread with water. I have found notable quantities of plaster of paris in certain tea-cakes of the muffin tribe, and in oat-cake.

"Copper sulpho-cyanide" (query 52680, p. 416) is of two colours. On mixing strong solutions of cupric sulphate and ammonium sulpho-cyanide, a black precipitate of cupric sulpho-cyanide $Cu''(CNS)_2$ is thrown down. This gradually changes to the more insoluble and stable white cuprous sulpho-cyanide $Cu'_2(CNS_2)$. Probably the reason why the solution of potassium sulpho-cyanide failed to give a precipitate, was that it happened to be weaker than that of the ammonium salt. On adding to the mixture a few drops of dilute acid and some sodium sulphite, white cuprous sulphocyanide will doubtless be thrown down.

"Extracting alcohol from oil" (query 52795) is, of course, impossible in ordinary cases. The only instance in which alcohol is met with as a constituent of oils, is when it has been purposely added to certain essential oils for purposes of adulteration. On adding a considerable pooportion of water and shaking, the alcohol is more or less perfectly removed. But oils liable to sophistication with alcohol are not fit for use as lubricants. Fancy using oil of bergamot, oil of anise, or otto of roses for lubricating machinery.

Sheffield, Feb. 9. **Alfred H. Allen.**

CALCULATIONS IN MECHANICS.

[22356.]—Some of "ours" may have noticed the complaint of the Science and Art Department examiner in "Applied Mechanics and Steam," that too many numerical questions are solved entirely by means of formulæ, and without the least reference to "first principles." Without doubt much of this is true; but I cannot help thinking that between the textbooks and practical questions there is a great gulf fixed.

If you, Sir, could find space, and some of your excellent correspondents time, for a few good letters on calculation of strains, &c., such as not to include the "calculus," I am sure they would be greatly appreciated by a large circle of readers.

Many of your readers must be extremely grateful for Mr. Marshall's articles on "Linkages." Cannot someone help us? **Egstow.**

A Brussels correspondent of the *Times* says it is seriously proposed at Antwerp to bring there during the Universal Exhibition in 1885 the *Great Eastern* as a floating restaurant and hotel.

REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[51631.]—**Transmission of Sound.**—The replies in number 966, to this query, and in number 964, are unsatisfactory. W. J. Lancaster states that the velocity of transmission in iron is 17 times greater than in air; therefore, iron transmitting low E does so by means of waves of iron measuring 476ft! What is this 476ft. the measure of? and what is the amplitude of these waves of iron? Stone's book, referred to by Mr. Grey, is inaccessible to me.—L. F. H., Queensland.

[52282.]—**Screw Press.**—Many thanks to A. Sugden for his reply to my query. The articles I make are clay pots, and for the larger size the stamp presses the clay 2½in. into a mould. To get the pot out of the mould, it is necessary that the stamp should be lifted 5in. As to the power required, I can only state that it can be worked by a lad of 16 years of age; but he takes a longer time than a man. The pressure is exerted through a distance of 2½in., the last turn of the screw requiring the greatest pressure. I should be glad to know whether I could, by some different adaptation of the screw, make a larger quantity of pots in the time.—J. B. T.

[52302.]—**Cheap Food.**—May I be permitted to reopen and answer some remarks on this question; press of work has kept me from answering them until now. Whole wheat is a very valuable food: its composition varies according to the place where grown; but we can give an average composition thus:—Water 15 p.c., carbonaceous matter 68 p.c., nitrogenous mattter 15 p.c., mineral matter 2 p.c. Thus, we see that it contains a large amount of carbonaceous material (for force and heat giving) and a good supply of nitrogen (for tissue repairing), and plenty of mineral matter (for bone making). It can be cooked very simply. Stewed wheat is thus made:—Soak your uncrushed wheat for a night in water, next day stew for four hours, and it is ready for eating. It can be eaten plain or with stewed prunes, raisins, or jam. Frumenty is the stewed wheat made into a porridge, with flour and a little spice, eaten with milk and sugar. Savoury wheat is made by stewing an onion with the wheat, then chopping the onion fine when it is cooked, return it to the pan (the onion flavour thus gets thoroughly into the wheat); lastly, add brown sauce, stew a few minutes longer, and serve up. This is eaten with potatoes and greens. and makes a good imitation of roast goose. The brown sauce comes in very useful for many dishes, as it acts as a condiment, so I will give the mode of preparing it. *Brown Sauce.*—Brown two ounces of butter or oil in a frying pan, add a dessertspoonful of flour, and stir till dark brown, then add seasoning and thin with hot water to the consistency of gravy. Pour into a gravy boat. Powdered herbs may be added to improve the sauce, and especially sage when using it for savoury wheat. *Savoury Rice* is prepared in the same way, and is also a cheap and nourishing food. Let readers try these dishes, and I will promise them an agreeable surprise. A word about the Esquimaux. These live on fish and flesh from necessity. They eat as much as 8lb. of flesh meat or 12lb. of fish at a meal, says Dr. John Rae, and a friend who lived amongst them 20 years tells me that they usually die from 35 to 45 of scrofula, the women living about 10 years more. He knew of only two men living to be 70. The Esquimaux eat the green contents of the reindeer's stomach, and in spring eat scurvy grass, wild turnips, wild vetch, wild oats, wild rice, sorrel, docks, &c. In autumn they eat wild prunes, blackberries, blueberries, crowberries, cranberries, &c. The women who gather these berries eat more of them than the men, and as my friend says, live longer in consequence, whilst the two men who lived to be near 70, lived as much as possible on these green stuffs and fruits. The Hudson's Bay Company allowed their men 8lb. of flesh daily, or 12lb. of fish, and no flour or anything else. Some were allowed 1lb. of flour and only 4lb. of flesh, showing 1lb. of flour to be equal to 4lb. of flesh, whilst some few were allowed daily 2lb. of Indian corn and ¼lb. of fat bacon. Substitute oil or butter for the bacon and these were vegetarians. The reindeer gets no animal food, yet it subsists well in these regions. These facts will, I hope, set at rest the Esquimaux difficulty. —T. R. Allinson, L.R.C.P.

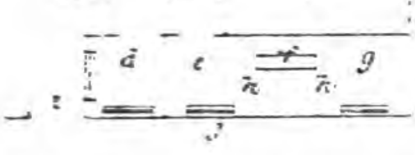
[52370.]—**Dynamo (U.Q.)**—I do not know of any rule; it is a matter for experiment. The E.M.F. produced in a coil of given resistance would vary with the size of coil, strength of field, speed of rotation, and several other factors; so you see how difficult it would be to form a rule. If you want a quantity current, put No. 16 on armature; if E.M.F., put No. 20. These sizes would do for a small machine. Of course with a larger machine you would get the same E.M.F. with less resistance.—W. H. F., Coventry.

[illegible]—**Gramme Armature (U.Q.)**—For a moderately strong field, about one-third of an inch; a very strong half inch. Get some thin linen and dip it in melted paraffin wax, wrap round ring while hot, and smoothe with hand; wind wire on this, and shellac each layer.—W. H. E., Coventry.

[52588.]—**Boring Holes in Glass.**—E. Holmes seems, like others, to have been troubled with the glass cracking in drilling a hole through it. To avoid this, the back of the glass should be sealing-waxed over, or a piece of stout paper, or something of the kind, glued on: the glass will not then crack. It is best to bore from both sides, so as to meet in the middle.—Edward Thos. Scott.

[52590.]—**Faulty Dynamo.**—A machine like yours would be rather difficult to wind so as to generate enough E.M.F. to light a 20c.p. lamp, unless you could get one with a very low resistance, about [illegible] ohms. If you will consider the conditions of machine when running you will see how this result is arrived at. The resistance of your F.M. is [illegible] ohms, and the resistance of A. ·5 ohm, and the external resistance best suited will be 2 ohms, very different to the resistance of a 20c.p. lamp. The machine ought to light four 10c.p. lamps in parallel arc. Re-winding F.M.'s as you suggest would not compensate for the trouble.—W. H. E., Coventry.

[illegible]—**Photometer. — Dark Room.** — *a* weighing-machine, *b* w.c., *c* photo room, *d* gatekeeper's lodge, *e* manager's room, *f* counter, *g*



office, [illegible] wooden partitions, [illegible] entrance, [illegible] frontage. Black your room with lampblack mixed with size and water.—[illegible] Assist. Eng., Gas Works, [illegible].

[illegible]—**Thimbles.**—If by thimbles the querist means the fingerstalls of the [illegible], they are stamped in the machine out of discs of thin sheet metal, passing through five or six different shaped dies, each more nearly approaching the finished shape, the metal being annealed between each operation.—Nun Dor.

[illegible]—**Rapid Lens Shutter.**—If this querist were a little more reasonable in his wants, he might find them satisfied in back volumes. Several such shutters have been described in recent numbers.—[illegible]

[illegible]—**Asbestos.**—If this is powder, it might be worked up into packing for engines or lining [illegible] [illegible] the [illegible] with which it is to be mixed will depend to some extent on the nature of the work to be done.—Nun Dor.

[illegible]—**Variations of Draught.**—You want an anemometer, which is a little fan in a cylinder; [illegible] will go to register the number of revolutions. [illegible] a good many careful experiments [illegible] will be able to form fairly accurate [illegible] [illegible] it would be better to have a [illegible] the [illegible] [illegible] to take the rate of travel of the gases [illegible]. If you can understand mathematics, see the chapter on "Chimney Draught" in [illegible] "Boiler and Factory Chimneys," published by Lockwood and Co.—Nun Dor.

[illegible]—**Working a Pump.**—The querist might try [illegible] windmill to work his pump with the [illegible] [illegible] intelligent village carpenter and the blacksmith. [illegible] that would not be sufficiently [illegible] [illegible] the wind does not come to [illegible] [illegible] might have a [illegible] engine [illegible] [illegible] might be induced to work [illegible] and would probably pump [illegible] [illegible] [illegible] If the querist [illegible] [illegible] [illegible] might be able to [illegible] [illegible] [illegible] [illegible] of well and the [illegible]

[illegible] in reference to what [illegible] [illegible] [illegible] I have [illegible]

[illegible] Bronze.—The Bronze [illegible] [illegible] bronze powder of the [illegible]

[illegible] —An answer to the [illegible]

query involves an explanation of the whole theory of colour. How far apart does Mr. Harcourt consider the "extreme limits of the spectrum"?—G. P.

[52635.]—**Singular Convulsions in a Child.** Only a medical man could give any definite opinion, and that only after examination. There is no special cause for alarm in the symptoms described, which may be due to worms.—F. M.

[52638.]—**Cement.**—Any dampproof glue, or good glue with a dose of vinegar.—T. J. M.

[52644.]—**Rusty Turpentine Tank.**—The cause is oxidation; its effect nil, except as to colour; the remedy, galvanising or tinning the tank.—S. R.

[52647.]—**Drainage.**—If the Local Board have control of a sewer which becomes blocked, and in consequence damages your property, you have a remedy against them. If they are sensible men, and their clerk does not want a case, they will appoint some of their number to assess the damage, and will then pay compensation.—Nun. Dor.

[52648.]—**Model Locomotive.**—"Amateur" will find the information he requires in back numbers (see, for instance, the Index to Vol. XXXII.), except that it is doubtful whether a pressure of 120lb. has been calculated for.—Essar.

[52649.]—**Varicose Veins.**—I have several times cured myself of this distressing complaint by taking care that everything about the foot and leg is quite loose, and, indeed, never suffer from it while nothing tight is worn. Let "Poor Sufferer" abjure boots and "elastics" of every description, and wear low Oxford shoes tied for walking as loosely as possible with ribbon, and when at home let them be untied, and very soon he will find himself comfortable. Socks must be worn (not stockings), and they must be very loose about the ankle. My last attack of varicose veins was brought on by wearing a pair of tight machine-made socks. A return to their old loosely-fitting predecessors soon cured me. It is singular that doctors (not having "like cures like" on the brain) should attempt to cure by tight clothing a complaint that is brought on by tight clothing.—K.

[52652.]—**Regenerative Burners.**—It has been frequently stated that the gas should be rendered as hot as possible as well as the air. See the illustrations of regenerative burners given in back numbers.—Nun. Dor.

[52672.]—**Sleeping with Aged Persons.**—Yes: I have always understood that it is very unhealthy, and something more. I knew a young lady who went as companion to an old person, and slept with her for a time, but she became quite ill: but recovered as soon as the doctor had her sleep alone, who said it was a very bad thing.—Edward Thos. Scott.

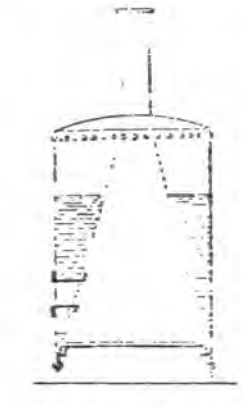
[52687.]—**Florida.**—"F." asks some questions concerning Florida (which I cannot answer), but at the bottom of his letter he asks for "advice about other States." I cannot ask the Editor to give me his space in which to restate the advantages West Dakota offers to the emigrant: but if "F." or any other readers of the "E. M." who are interested, will write to me, inclosing a penny stamp to recoup me for postage, I will send them some literature that will give a deal of valuable information. I am not interested in any railroad scheme, nor do I own enough Dakota soil to induce me to delude my fellow-countrymen.—R. M. Tuttle. Mandan, Dakota, U.S.A.

[52755.]—**Bath Heater.**—I am obliged to Mr. Fletcher and Mr. Bousfield for their replies: but, as yet, no practical information is forthcoming as to how the temperature of 40 gallons of water can be raised to [illegible], for a warm bath, in less time than [illegible] hour. Neither my supply of gas nor water is deficient, as is suggested: and "An Old Subscriber's" remarks on this subject as to the necessity for having a [illegible]in. service-pipe with a 120-light meter, to obtain the results of Mr. Bousfield, show the utter inutility of adopting any such arrangement for a small private bath-room.—H. H.

[illegible]—**Steam Launch.**—Would Thomas Thompson mind putting the size, &c., of engine in the "E. M." for the sake of other readers?—[illegible]

[illegible]—**Knocking inside Cylinder.**—The "knock" may arise from a variety of causes—e.g., piston loose on rod; piston rod touching bottom of cylinder; no compression at bottom; &c., &c. It is impossible to assign a cause to it without a thorough examination, but if "Engineer Jack" will advertise his address, I shall be happy to render him all the assistance I can in getting rid of the noise. The result of leaky air-pump valves and drawing air through the gland is defective vacuum.—Labor Omnia Vincit.

[illegible]—**Boiler for Model Engine.**—The boiler of which I inclose a rough sketch is made as follows:—Body of sheet brass or copper [illegible] thick, [illegible]in. diam., [illegible]in. high, a dome-shaped top flanged down ⅜in. all round, to fit tightly inside [illegible] of body, which must be riveted up the seam: [illegible] top must also be riveted in, after which the [illegible] and rivet-heads should be thoroughly solder-[illegible] inside. The firebox is made of copper and is conical in shape, it should be brazed up the seam, and be of such diameter that it fits the boiler tightly at bottom, and it should taper to 1¼in. at top. The funnel is of copper brazed, 1⅛in. diam, and about 5in. high. The firebox is riveted to the boiler round the bottom. The top of boiler is flanged up in the centre round the hole for the top of firebox about ¼in., the top [illegible]



firebox is then flanged down outwardly over the [illegible] of boiler, and well planished down all round; this makes a very strong joint. The firedoor ring is put in in a somewhat similar manner, as will be seen from the sketch. I have made several boilers on the above plan of different sizes, and have always found them answer capitally. They burn coal splendidly, and get up plenty of steam. I am unable to say what the cost of making one would be, as I make mine myself, but they require careful workmanship.—C. E. B.

[52823.]—**Electric Lamp.**—I know of no lamp suited to the purpose unless you have power always available equal to, at all events, 20 Bunsens or bichromates. These, with a 16-candle Swan lamp, will serve.—Sigma.

[52833.]—**Water Heater.**—I am not a "legal" man: but if I may offer any advice on this point, I would say, heat the feed water by all means if you want to save coal. There are various kinds of water heaters made where the steam is passed through a coil or a number of brass or copper tubes, and are arranged so that the interior can be easily cleaned. By using a heater and frequently removing the mud from inside, there will be less deposit in boiler. I could lend you a drawing of one I have in use if you advertise your address.—Labor Omnia Vincit.

[52840.]—**Core Box for Globe Valve.**—To "J. H."—Thanks for your offer of assistance. The description of the valve you give is exactly what I mean. They are made largely in brass for connections for malleable iron pipe, and what set me inquiring was seeing some made by Cooper Jones and Cadbury, of Philadelphia. How they are cored I cannot understand very well. I am a patternmaker, so that I can easily do the work if I know what is wanted.—Quebquen.

[52845.]—**Law respecting Churchyards.**—"F. R. C." cannot do better than get "The Book of Church Law," by the Rev. J. H. Blunt, M.A., published by Rivingtons, price 7s. 6d. The body cannot be removed without a "faculty."—Curate.

[52855.]—**Vibration Number of Whistle.**—An open organ-pipe or whistle 2ft. long, corresponds in pitch to the note of Middle C of the piano. I think "Student" must have made some mistake whilst comparing the pitches of his whistle and middle C of the piano. His calculation is correctly worked out.—Cymro.

[52863.]—**Removing Caps from Green's Economiser.**—Saturate the caps with petroleum and you will have no difficulty in removing them. All corroded joints and bolts should be so treated.—J. F. W.

[52867.]—**Feed Pump.**—Respecting "Fire's" reply to the above query, in case the stroke of ram is not 1ft., how will he work it out? As a case in point, what would be delivery of a ram 4in. dia., 8in. stroke, 50 strokes per minute? Has "Fire" noticed my query re Green's Economiser, and can he assist me?—Simplex.

[illegible]—**Electro-motor.**—No single cell of any kind would do the required work, and certainly not a Daniell. All the Leclanché forms are useless for such work, and it would require at least five bichromates.—Sigma.

[illegible]—**Battery.**—To "Kosmos."—In reply, 1. Yes. 2. I was not aware that the chloride of zinc or am. battery could be strictly termed a bichromate, or I should not have expected my battery to last so long. My bichom. sol. is saturated + ⅛ muriatic acid; if I added more acid and less solution to outer cell, would it tend to lengthen or shorten the battery's life, or if I add muriatic acid to ch. of am. of porous pot, will that lengthen the useful period? 3. I do not think so. I have found the Leclanché more troublesome in the long run, and I require considerable power, as I work two needle instruments, six bells, and three indicators on the four cells chloride. Your further reply will be esteemed by—R. Hannen.

[52878.]—**Analysis of Coal-Tar.**—There is not, I believe, any book treating specially on this analysis; but valuable information respecting coal-tar products may be obtained on reference to "Commercial Organic Analysis," A. H. Allen; there is also a book by Lunge, which may possibly be of use to the querist. Coal-tar contains many exceedingly complex bodies, and it is not to be wondered at that many yet remain undiscovered, and those capable of estimation being in some cases but approximate.—J. C. Belcher.

[52878.]—**Analysis of Coal-Tar.**—Tar is too complicated a mixture to be subjected to regular chemical analysis. The only reliable method of testing a coal tar (and the one generally used by tar distillers) is to distil a small quantity of it, say, 20 to 30 gallons, in a small still reserved for that purpose. It is thus separated into different parts, which are weighed and then tested separately for the constituents which it is intended to extract from them. Tar contains on an average 0·6 per cent. benzine, 0·4 toluene, 0·5 xylene, and other hydrocarbons of the benzine series—8 to 12 per cent. naphthalene, 5 to 6 per cent. phenol, 0·25 to 0·3 per cent. anthracene. If "Augustus" would tell me which of these bodies chiefly interest him, I shall be glad to explain how and where to look for it.—Organic Chemist.

[52879.]—**Analysis of Oilcake.**—Church's "Laboratory Guide" furnishes the desired information. The process is somewhat lengthy, or I would describe it.—J. C. Belcher.

[52879.]—**Analysis of Oilcake.**—Oilcake is chiefly used as food for cattle. Its analysis ought therefore to show its value as such, as well as the quantity of residual fatty oil contained in it. To make an analysis of oilcake, powder it finely, then heat a weighed quantity to 100 to 110° C. in a drying chest until it assumes constant weight. The loss it sustains represents the water. Introduce a weighed quantity of the dried material into an extracting apparatus, and extract with ether for two to three hours. Drive off the ether and weigh the remaining fatty oil. The residue from the extraction may be carefully dried at 100° C. to get rid of the ether, &c. It may then be tested for nitrogen by the well-known soda-lime process. From the quantity of nitrogen obtained a fair estimate may be made of the quantity of albuminoid (nutritive) matter present in the oilcake.—Organic Chemist.

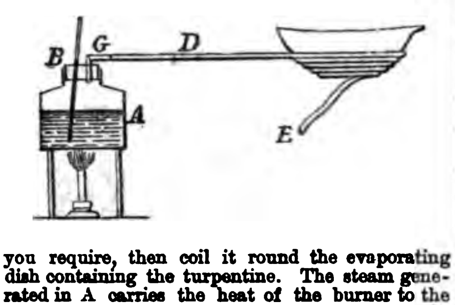
[52884.]—**Engine Query.**—The only way out of your difficulty is to raise the boiler to the engine level. You can reduce the condensation by coating the pipe with a good non-conducting material. Also fit a tap in the steam-pipe, near the engine, which should be opened for a few moments when starting her. I presume the highest point of your boiler is 6ft. below the engine.—J. F. W.

[52885.]—**Ancient Lights.**—My best thanks to "Ditton." Will he kindly give a little more information? I want to know the position of the angle—e.g., a line perpendicular to the plane of the wall containing the "light," being one of the legs of a right-angled triangle, which is also isosceles, forms an angle of 45° with the hypothenuse at that point; but where is the position of the angle situated? Is it at the base of the wall—i.e., on the ground plane or at the window-sill? which latter may be 3ft., 20ft., or possibly 50ft. from the ground, which distance constitutes a vast difference.—Old Ploughman.

[52886.]—**Dynamo.**—Certainly the addition of the iron ends is a most effectual way to destroy the power of the armature to produce currents; they should be gun-metal. I have not time at present to consider whether other causes of failure exist in the proportions, and should say put that right first.—Sigma.

[52892.] — **Polishing Paste.** — The German polishing pomatum you speak of is prepared by grinding together ferric oxide (*caput mortuum*) with tallow, adding a little mirbane to cover the smell of the tallow. The best *caput mortuum* for polishing purposes is obtained by precipitating a solution of ferrous sulphate with oxalic acid, and subsequent ignition of the well-washed crystalline precipitate. This preparation, however, is too expensive for the manufacturers of polishing paste, who use the common article of commerce, or even the still cheaper residue of pyrites obtained in the manufacture of sulphuric acid. — Organic Chemist.

[52900.]—**Water, Steam, or Sand Bath.**—The following plan will probably suit your purposes. Obtain a tin can, A, capable of holding, say, half a gallon of water, and fit it with a good cork carrying safety tube (B) and steam-tube, G, both made of glass. Fill the can half-full with water, and apply heat by means of a powerful Bunsen burner; connect G by means of an indiarubber joint, with an ⅛in. leaden pipe; carry the latter straight as far as you require, then coil it round the evaporating dish containing the turpentine. The steam generated in A carries the heat of the burner to the evaporating dish, and escapes at E, almost entirely condensed. The arrangement may be improved by surrounding the leaden core with some non-conducting material, such as woollen rags, sand, &c. You may also immerse the core into the liquid if there is no fear of an action of the latter on the metal.—Organic Chemist.



[52909.]—**Barlow's Wheel.**—"E. D." will find the action of this a case of "rectilinear repulsion" (Guthrie, p. 240). When a point of the wheel touches the mercury in the trough the circuit is completed, and the point "moves away from the resistance," if I may use such a phrase. If the points be too deep in the trough, I have often found the current unable to overcome the inertia; but even then, on starting the wheel by hand, it will continue turning. The copper disc wheel is only a particular case of the stellar wheel—is, in fact, a stellar wheel with an infinite number of points.—Egstow.

[52914.]—**Dynamo.**—In reply to this query, Mr. Bottone has, on p. 102, "An ammeter (or current measurer) consists essentially of a galvanometer wound with a very large quantity of very fine wire, so that the resistance in the instrument is infinitely greater than the resistance in the dynamo; but such instruments are very misleading. Such an instrument, if used in the main circuit as an ammeter, would indeed be very misleading. All the ammeters that I have ever seen or heard of have a coil of as low resistance as possible; in fact most of them have simply a broad copper band underneath the needle. Mr. Bottone must have been thinking of a voltmeter.—Electro, Manchester.

[52918.]—**Transmitter.**—The lead weights are put on the pieces of wood attached to the carbon cones to act as ballast and keep the cones upright. Sheet flattened out, or a small strip cut from a piece of sheet lead, will do. I used lead wire because I had it at hand; it can be obtained from the seedsmen, as it is used for tying up plants. This microphone works by the difference in the vibrations of the various parts; by making one of the pieces of wood attached to the cones longer than the other, it alters the rate of vibration of that one; the consequence is that the two cones respond to different vibrations, and the articulation is much improved. This microphone, though it only transmits speech when spoken to, transmits every note of a piano played in the room in which it is fixed, and with an unusual freedom from burr. My clear-speaking receiver is both described and illustrated in the Mechanic of the 29th June last. It is patented, and cannot therefore be lawfully used without a license. I hope soon to arrange for the granting of licenses at such a very moderate royalty, as will bring the telephone into general use, and will make it a popular instrument.—H. B. T. Strangways.

[52926.]—**Double-Cell Bichromate Battery.**—I do not know why such a deposit should form if the solution contains free acid; nor do I remember to have ever been troubled with it. There must be impurity or bad arrangements.—Sigma.

[52927.] — **Watchwork.** — Your watch most probably winds up too far, and by so doing takes all power off the train. See to the stopwork, and also see that the chain is the proper size. Take the watch to pieces, try the chain on the fusee without the plates, and when you have filled the groove in the fusee, you should have about fourteen links and the hook left. If the chain be too long, make it the size stated, then try it in the plates, and see that when it is wound up the stop holds it properly; also see that the fusee arbor is free between the plates; put a drop of oil in the barrel with the mainspring, and you will see that your watch will work if all the train, &c., be right.—Hamlet.

[52929.]—**Engine Query.**—If this querist is the same that I replied to on page 394, query 52550, he was there told to have his engines indicated in order to find out the power exerted. Moreover, in the original query the sizes given are very different to those in the last query. Look here, "Engineman." Have those engines indicated, and find the mean average pres. on each piston, and then multiply the area of the cyl. by the average pres., by the speed of piston in feet per minute, and divide by 33,000; the quotient is the h.p. exerted by that engine; and next time you ask a query, be sure the dimensions you send are correct.—Labor Omnia Vincit.

[52932.]—**Delirium Tremens.**—In answer to "Cymru" one may say that pain is never accompanied by pleasing thoughts or visions, save where a person has been suffering martyrdom for a great cause. The disease of delirium tremens is a painful one, attended by great nervous weakness and fear, and the concomitant visions are of a fearful nature. The visions seen in dreams and delirium tremens are allied phenomena. No one, however, would expect a sleeper to see pleasant dreams if a mustard plaster were applied to the top of his head; but he might imagine some fearful thing as, *e.g.*, that he was being scalped by wild Indians, and he would certainly not have pleasant and happy dreams. So likewise the sufferer from delirium tremens builds up frightful images in his disordered brain as the result of its disorder. Nor could one expect him to see anything pleasing under the circumstances, no more than one would expect a child passing some dark and lonely nook, in fear and trembling, would see in the darkness friendly faces instead of hobgoblins. For a discussion of the nature of delirium tremens, I may be allowed to refer "Cymru" to my recent work on "The History and Science of Drunkenness" (London: Simpkin, Marshall and Co.).—William Ackroyd.

[52938.]—**Heating of Journals.**—If "Apprentice" will state whether the shaft is steel or iron, and will apply to Osborne and Co., Limited (see advertisement facing first page of matter), he can be supplied with the requisite composition for his purpose.—A. L.

[52940.]—**Gas Stoves.**—The iron flue is carried only in the parts where it is cool enough to condense the products of combustion, which contain a trace of sulphuric acid. There is no remedy except to use copper or pottery ware tubes in the colder parts of the flue. The stove will probably be hotter than boiling water all over, and there will therefore be no condensation and consequent rust.—T. F.

[52943.]—**Electro-Magnets.**—To prevent the armature sticking, solder a thin piece of copper on the poles of your magnet.—M. Seymour.

[52943.]—**Electro-Magnets.**—"C. B." only wants Nature to alter her system for his convenience. With an armature in actual contact, residuary magnetism is great. The only remedy is to prevent contact. A good plan is to tin the face of the magnet, or deposit copper or silver; but, of course, this rather lowers holding powers, though not the attractive power.—Sigma.

[52943.]—**Electro - Magnets.** — "C. B.'s" magnet is, I should say, not soft enough. If the wire is wound on reels and slipped over the poles, I should advise removing the reels and leaving the iron horseshoe in a clear fire all night. He might, however, first try the effect of sticking one thickness of thin paper over the poles, so that the armature will not actually touch the magnet.—B. H.

[52943.]—**Electro-Magnets.**—The reason the armature adheres to the poles, is that the iron of the magnet or armature is not soft enough, and consequently retains permanently some magnetism. Even if the magnet were composed of the softest iron obtainable, some of the magnetism would still remain for a time, and, in fact, the residual magnetism is never fully eliminated. The armature can be made to release, when the current is stopped, by using a spring to counterbalance the attractive effect of the magnetism.—Electro, Manchester.

[52943.]—**Electro-Magnets.**—Your magnet is not made of sufficiently soft iron. Take off the wire and put the iron into the fire. While it is getting red hot make a nice little hole amongst the cinders in the grate, in which, when red hot, you must bury it. It must be left among the ashes till quite cold, and on no account must it be cooled quickly. You will find this answer perfectly well. Far from injuring the "holding power" of the magnet, it will increase it, for soft iron is always more strongly magnetised by the current than when not annealed.—R. A. R. Bennett.

[52945.] — **Oxidising Copper Wire in Battery.**—The sal-ammoniac forms chloride of copper, which is bright green. You should use iron wire coated with indiarubber, which can be dissolved in naphtha, and well painted on.—M. Seymour.

[52946.]—**Lightening a Wife's Duties.**—Try a small windmill and pump.—M. Seymour.

[52946.]—**Lightening a Wife's Domestic Duties.**—As the required quantity of water only amounts to a bucketful a day, raised to the height of one story, it appears that the simplest plan would be to invest a shilling in a bucket and carry it up full each morning. If the querist can drop on a second-hand beer engine, and fit it up with a pipe leading to the cistern, the water might be pulled up half a pint at a time, if desired, without much trouble.—SIGMA.

[52945.]—**Lightening a Wife's Domestic Duties.**—If "A Reformed Partner" will further reform himself and carry up the 20lb. weight of water which his wife requires daily, he will have a reliable apparatus which will cost nothing, and need no fixing. Little and cheap pumps are to be bought in any quantity; but if no fixtures are allowed, it is hard to see how a satisfactory arrangement could be made. It would certainly be cheaper to pay a penny for having a bucketful carried up than for a lodger to spend, say, 30s or 40s. on a pump.—T. F.

[52948.]—**Banjo.**—(1) Ballantine's "Banjo Tutor," to be obtained at John Alvey Turner's, Crosby Hall, London, E.C., is the best book on the six-stringed banjo (price 1s. 6d.) (2) You can get the proper sized strings of the best quality at Turner's. The first string should be a fine violin E; second, a violin thick E; third, a violin second A; fourth, a violin third D; fifth, a fine silver-covered gut string; and the sixth, a violin E, like the first. (3) The tips of the first and second finger should be nearer the bridge than the tip of the thumb. The further you can get them back from the thumb, the better the tone produced.—H. B. G.

[52948.]—**Banjo.**—(1) In my experience the best banjo tutor for a six-stringed banjo is Ballantine's, which is published by John A. Turner, 33, Bishopsgate-street Within (Crosby Hall), price 1s. 6d. (2) The correct strings are as follows:—The first should be violin first E; second, violin second or thick first E; third, violin second A; fourth, violin third D; fifth, fine silver-covered gut string; sixth, violin E, like first. (3) I always strike notes with the tip of the forefinger, nearer the bridge than the thumb in striking notes with the forefinger and thumb together. I think you will find the banjo tutor I mention the very thing you want.—T. M. COOMS.

[52950.]—**To Violinists.**—The breaking of strings may be caused by the violin being improperly set up, and I would advise querist to get some experienced violinist who would arrange bridge, &c. The finger-nails should also be pared closely. I hardly know what to say about the shortness of little finger. Are you sure you hold the violin rightly? The palm of the hand must not touch the neck of violin. The wrist must be thrown back, bringing the fingers vertically over the strings. Schubert's Violin School, Vol. I., Littolff Ed., shows the position very well.—SPOHR.

[52951.]—**Smith's Forge.**—"Young Country Smith" should make the hole in his tue iron 1in. diameter for bellows 36in. broad, and, if possible, use coke in place of coal, although we find much of the coke made from Staffordshire coal makes much dross and scale, which adheres to the iron when heated to a welding heat. Also let him fix his tue iron to stand 3in. from the wall of his hearth to the nose of tuyeres.—BASSO.

[52952.]—**Loss of Voice.**—Querist should have mentioned his or her sex, as in females loss of voice is often a phase of hysteria. I should advise querist to have the throat examined with the laryngoscope. The condition is very probably due to swelling of the mucous membrane covering the vocal cords, for the relief of which astringents must be applied directly to them. On the other hand, it may be due to paralysis of one or both cords and require constitutional treatment.—M. D.

[52952.]—**Loss of Voice.**—"M. L." must swallow three raw eggs per day to restore the organs of voice to healthy action. I had been speaking in whispers for two weeks when "A Wise Woman" advised me as above, and five eggs effected a cure, verifying the truth of the nursery rhyme about the woman sucking "birds' eggs to make her voice clear." The more newly-laid you can obtain them the more curative and the sweeter they will be. Break the yolk, but it need not be beaten up. No condiment is required.—H. O'B.

[52954.]—**Hand Water Tap.**—Cannot Arnold Waterfield do as he requires by using the end of a rubber tube as the jet, and turning off the water by pinching the tube?—T. F.

[52954.]—**Hand Water Tap.**—For such a purpose nothing is better than a piece of soft rubber pipe held between finger and thumb. If more elaborate plan is desired, place the pipe between the two parts of a jointed lever, like a pair of nut-crackers, with a rack at the end, under which the movable arm can be slipped when not in action.—SIGMA.

[52958.]—**Ancient Lights.**—The "45° line of light" is [illegible], and if the new building is built so as to make [illegible] angle with the "ancient light" an injunction may still be granted if a material diminution of light be proved. The angle of 45° is measured from the bottom edge of the "ancient light," so that if the distance between it and the new building be as great as the height of the new building above the bottom edge of the "ancient light," then "the 45° line of light" is preserved.—JOHN P. OSBORNE, Birmingham.

[52959.]—**Beer in Scratch-brushing.**—If "W. H. H." means sour beer, a little vinegar and treacle should give the same result.—T. F.

[52959.]—**Beer in Scratch-brushing.**—Use a mixture of the following: ½ pint of oatmeal boiled in two quarts of water, strain, and then add ½ pint of strong vinegar.—M. SEYMOUR.

[52960.]—**Silk Flaps on Plate Machine.**—You should use lard, not olive oil; only one thickness of silk.—M. SEYMOUR.

[52960.]—**Plate Machine.**—Why use oil? Oiled silk is certainly recommended outside the plain black silk; but oiled silk is a well-known dry preparation—not silk wetted with oil. You can get it at any chemist's.—SIGMA.

[52960.]—**Plate Machine, Silk Flaps.**—The silk flaps are stitched on to the rubber. Only one layer of silk is used. Neither the rubber nor flaps should have any oil whatever applied to them. What "W. H. H." has mistaken for the real silk flaps are simply pieces of oil silk, sometimes put on to protect the real flaps, which are underneath.—ELECTRO, Manchester.

[52961.]—**Butterflies.**—Dip the whole insect into chloroform, and leave it for a few minutes to get thoroughly soaked. When taken out it will be found to be "relaxed." Set it while soaking wet. It will dry in a few minutes, and remain set as you put it. This will answer well if properly done. The effect of the chloroform on the colours is alarming, but they all come back as brightly as before when dry. "Lu" had better practise on a few common butterflies first.—R. A. R. BENNETT.

[52961.]—**Butterflies.**—A safe way of relaxing these insects is to float them on a piece of sheet cork in a basin of water, over which a wet cloth is to be stretched, making the interior as nearly air-tight as possible. It is a good plan to place a slip of wood or cardboard over the cork, thus preventing the water from soaking through to the insects, and care must be taken that the cloth is not too wet, or drops will collect and fall upon the butterflies. Many small species will, by this means, be relaxed in twenty-four hours, larger ones taking longer, in proportion to their size. Very delicate handling must be exercised. After relaxing, they will require fixing upon proper setting-boards, and much of their value depends upon the success of this process. If "Lu" likes to send me seven specimens, I shall be pleased to return him six properly relaxed and set, keeping the seventh for my pains.—MARTIN J. HARDING, Old Bank, Shrewsbury.

[52961.]—**Butterflies.**—For relaxing insects that have once dried there is no rapid method of any use. The following is the very simple mode adopted by myself, and I believe also by most entomologists, who frequently have more specimens than they can properly set in the summer, and who allow them to dry till they can give them more careful attention in the slack season of winter. An ordinary soup plate is filled with sand; this is made thoroughly wet, surplus water being drained off. A thin sheet of cork, on to which the insects to be relaxed are pinned, is laid on this wet sand, and a finger glass reversed over them. Some insects will take as much as three or four days to become sufficiently soft to set, and must not be taken off the setting boards till thoroughly dry, requiring another two or three days for that purpose. Reset insects have, however, one great peculiarity—namely, a tendency to spring back after a time to the position in which they originally dried. To avoid this when the insect is satisfactorily set, it should be removed from the board, and just touched underneath where the wings unite with the body, with a cement made of shellac dissolved in spirits. The point of a knitting needle is about the most convenient thing with which to apply the cement. After this is done, the insect should be replaced on a setting board with a very wide groove to prevent the cement touching the board, and be strapped down for another day till the cement is quite hard. For relaxing, ordinary winebottle corks, stuck end in to the damp sand, answer admirably, and take just one insect each.—A. LLOYD.

[52965.]—**Regulator for Shocking Coil.**—"Mungo" can regulate his shocking coil by having a brass or copper tube to slide over the iron core. The greater the length of core inclosed by the tube, the less will be the effect in the regulator. He may also use a water regulator consisting of a glass tube, with a brass cap each end, and a sliding brass rod through one cap. The tube is filled with water, and the terminals of secondary connected to the caps. By varying of rod immersed in the liquid, the current may be regulated.—ELECTRO, Manchester.

[52967.]—**Hydrogen Peroxide.**—This article is a commercial article, and can be bought in 10 or 12 volume solutions, cheaply, and therefore your latter queries do not need answering. It is a powerful oxidising agent, and the best that can be used where other ingredients are objectionable, such as manganese and lime.—GEO. G. BLACKWELL.

[52968.]—**Slide Valves.**—"Formula" will find the following in Ainsley's "Engineer's Manual" and a great deal more information that would be useful to him: L = lap steam side = $1\frac{1}{2}$in.; l = lap exhaust side = $\frac{1}{4}$in.; D = lead = $\frac{1}{8}$in. The $(L + D) - l$. Thus, distance from mid position to where open for lead = $1\frac{1}{2} + \frac{1}{8} = 1\frac{5}{8}$; exhaust port open = $1\frac{5}{8} - \frac{1}{4} = 1\frac{3}{8}$in.—W. ROU[illegible].

[52969.]—**Chloride Battery.**—The proper charge for "chloride" battery is:—Inner cell, $1\frac{1}{2}$oz. chloride of zinc; outer cell, saturated solution of potassic bichromate, 2 parts; hydrochloric acid, 1 part. A little mercury at the bottom of the inner cell.—R. A. R. BENNETT.

[52971.]—**Antimonial Lead.**—Dissolve your antimony in nitric acid, then add excess of ammonia, and afterwards hydrosulphide of ammonium, which has had a small quantity of flowers of sulphur added. The precipitate digested at a moderate heat is gathered upon a filter, washed with water containing a little hydrosulphide of ammonia. The filtered liquid containing the antimony should have a little acetic acid added; the sulphide of antimony precipitates, and is gathered, washed, dried, and weighed.—M. SEYMOUR.

[52972.]—**Turning Stone.**—In answer to Geordy Black, he does not give the size of pillars, so that it is impossible to say whether they will require iron centres. If they are not very long, and thick enough to bear turning, they will not require them; but, perhaps he means simply centres for fixing on lathe-nozzle and poppet. If so, they will require them. Tools used for turning iron are not suitable. A bar of steel 2ft. or 2ft. 6in. long drawn out to a sharp point much longer than point used for metal will be the best tool, and either turn dry or use a little water. As to polish, I never heard of such a thing as polishing sandstone. He might varnish them, but that would not be a real polish. After turning as fine as possible, grind with sand and water, and, if wanted fine, finish with fine emery and water.—W. POTTS.

[52973.]—**Sharpening Circular Cutters.**—I think what is alluded to in your inquiry is the process of sharpening the above by emery wheels if the teeth on the cutter are not too fine in pitch. Circular saws, cutters, and a variety of machine knives are ground by these stones, and, with care, are quite equal to a file-finished job.—WILLIAMS.

[52973.]—**Sharpening Circular Cutter.**—I have used for years the small corundum wheels made for dentists, run at a slow speed, with plenty of water, and these were adopted by the L. and N.W.R. at Crewe at my suggestion. I believe now that small emery wheels can be got made to special sections for the purpose. These can be run so as to cut quicker than the corundum wheels.—T. F.

[52976.]—**Bleaching Horsehair.**—You will never get this white without destroying it; but first well boil it, and while still hot dip it in hydric peroxide.—M. SEYMOUR.

[52978.]—**Dynamo Machine.**—I suppose the compound Siemens armature means the usual Siemens dynamo, of which I gave a diagram of the winding in a recent number. What "J. P. M." asks me for is simply to furnish an essay on the subject, and give up a couple of days' work to the matter. He must content himself with such information as Mr. Bottone is giving, or as may be found in various books. It is not possible to furnish fresh particulars to each separate person who wants to make a dynamo.—SIGMA.

[52979.]—**Railway Keys.**—I know a little about the M.R. system with keys placed inside, and have had cause to complain about them some years ago on account of the wheel-flanges running on them, which causes them to be quite sharp. When tyres get run down, the flanges get deeper, and so run on the chairs. This is, I have no doubt, the reason for changing them to the outside, so the wheels will run longer without turning up.—LOCO.

[52980.]—**Crescent Moon.**—In reference to Arthur Mee's query on this subject, it is stated in the *Intellectual Observer*, Vol. VII. p. 240, that an observer at Runcorn observed the moon on [illegible] February, 1864, when it was little more than [illegible] hours old. On January 28th, 1865, Mr. D. J. Freeman saw it at Mentone when it was 32 hours old, and was informed by an inhabitant of the place that some years previously he saw the thin crescent of the *old* moon above the horizon before sunrise, and on the evening of the same day saw the thin crescent of the *new* moon soon after sunset. Mädler saw it 18 hours before conjunction on October 1st, 1834.—THOS. GWYN ELGER.

[52985.]—**Legal.**—In reply to G. Russell Pri[illegible]ham, the Act of Parliament compelling a father, grandfather, mother, grandmother, or child of a pauper to support him, is the 43 Eliz. c. 2, s. 7.—B. H.

ANSWERED QUERIES.

umbers and titles of queries which remain unan- 'or five weeks are inserted in this list, and if still red are repeated four weeks afterwards. We trust ers will look over the list and send what information for the benefit of their fellow contributors.

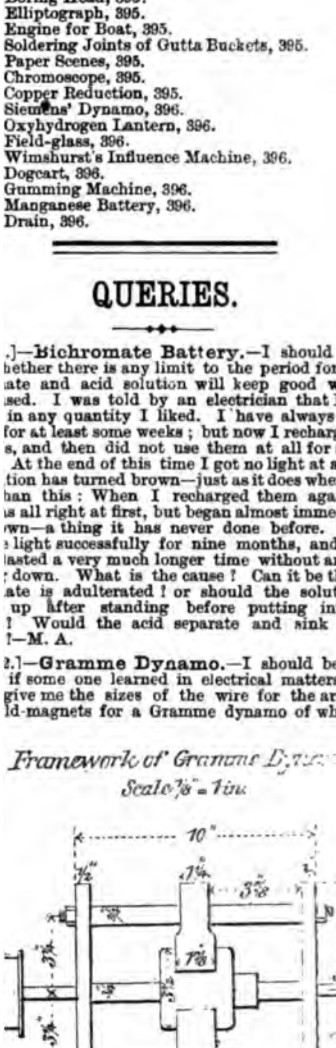
QUERIES.

.]—**Bichromate Battery.**—I should like to hether there is any limit to the period for which ate and acid solution will keep good without sed. I was told by an electrician that I could in any quantity I liked. I have always found for at least some weeks; but now I recharged my s, and then did not use them at all for several At the end of this time I got no light at all, and tion has turned brown—just as it does when used. han this: When I recharged them again, the s all right at first, but began almost immediately wn—a thing it has never done before. I have light successfully for nine months, and it has lasted a very much longer time without any sign down. What is the cause? Can it be that the ate is adulterated? or should the solution be up after standing before putting into the ? Would the acid separate and sink to the ?—M. A.

2.]—**Gramme Dynamo.**—I should be much if some one learned in electrical matters would give me the sizes of the wire for the armature ld-magnets for a Gramme dynamo of which the

Framework of Gramme Dynamo.
Scale 7/8" = 1in.



Section.

gives the principal dimensions of the framework y made. What should be the relative resistances ring and field-magnets, and what would be the ble lighting power, and the amount of h.p. ed in driving it? Into how many segments would est to divide the ring?—D'Elgo.

83.] — **Melting Tallow.**—Would "London " kindly explain how rough tallow is melted by and sulphuric acid? I have tried, but find tha ter, fat, and acid combine into a kind of soup, from which the fat will not separate. The steam was blown in, and the material was damaged hams. The débris fell to the bottom, taking the fat with it. A chemist told me it was albumen caused the bother. What is the remedy?—Country Workman.

[52984.]—**Chilled Castings.**—I have a number of cast-iron rims of wheels to make, that are required to be chilled on the outside from 5-16in. to ⅜in. deep. They are about 2in. wide. I can only get a chill on them of about ⅛in. I should be glad if any of our correspondents could help me as to what kind of iron I should use, &c.? There are no arms or centres in them to interfere with the contraction.—One in the Trade.

[52985.]—**New Synchronised Clock and Time Signals at the British Horological Institute, Soho.**—Can our esteemed friend, Mr. Baldwin, or others, oblige us with a description, with sketch, of the above? Also, if we can make same to exhibit in shop window?—Several Shopkeepers.

[52986.]—**Lightning Conductors.**—Can "Sigma," Mr. W. J. Lancaster, or any of "ours," give me any information as to lightning conductors as erected upon Houses of Parliament? By whom erected? What kind, and how long since they were tested?—Conductor.

[52987.]—**Nickel Plating.**—I am fixing up a small apparatus for nickel-plating. Will some of your contributors kindly give the composition of nickel solution? —E. W. N.

[52988.]—**Paint Manufacture.**—Can any of your readers furnish information as to the plant necessary for this manufacture? Possibly some one may be able to give reference to some book treating upon the subject. What is considered to be the best m terial at the present day for coating the bottoms of iron vessels?—Eothen.

[52989.]—**Lead-lined Outer Vessel for Battery.** —Large glass vessels being too expensive and too breakable, I intend using wooden rectangular boxes 10in. by 5in. by 9in. deep, which I cannot make watertight, and line them with sheet lead ¾mm. thick (corresponding, I suppose, to, say, No. 21—22 B.W.G.). I have vainly tried to solder the plates together at the joints—scraping first the lead, then rubbing it with a tallow candle, and pouring molten lead on the joints. The lead does not stick, and at some places melts the sheet away. What should I do?—Belgian.

[52990.]—**Siemens I Armature.**—Will any one give the correct section of this piece? I intend getting one cast in malleable iron 5¼in. long and 1½in. diameter. Are these proportions right?—Belgian.

[52991.]—**Metal Turning.**—Will any one advise a good practical book upon lathework for an amateur's use?—making the tools, grinding them, &c. "J. H." would certainly oblige a quantity of amateurs by sending letters upon this subject.—Belgian.

[52992.]—**Slide-rest to turn Cones.**—I have a 5in. screw-cutting lathe, and want to graduate my rest to all useful degrees. I wish above all to know how to ascertain when the short side-sliding motion is parallel to the centre line?—Belgian.

[52993.]—**1 H.P. Boiler.**—I want to make one as compact as possible with, say, 12 locomotive copper tubes inside. An engine is all very well; but boilers are seldom advertised, and if an estimate be asked, prices are very little different from that of the engine itself, if not higher.—Belgian.

[52994.]—**To S. R. Bottone.**—Would you kindly give an estimate of first cost for making a motor, and hourly expense for working it, to drive properly a 5in. back-geared lathe, with a battery which I leave to your judgment to advise.—Belgian.

[52995.]—**Pressure of Water.**—Can any of our readers tell me—Is the pressure of the water at the bottom of the sea much greater than at the surface? If so, how can it be calculated without algebra? Or, putting it simply, what would be the pressure on the sides of an air-bladder at different depths?—Practice.

[52996.]—**Brick-Glaze.**—Is it possible to get a white glaze on common bricks by any means? Could I manage any other colour? Perhaps some of our "chemistry" friends will suggest, and I should be glad to experiment, and be thankful. Is there any book on the subject?—Brickmaker.

[52997.]—**Legal.**—A. leaves by will value in shares, &c., to be divided in certain proportions among his brothers at the death of his wife. In the case of one brother, he dies about the same time as the widow, and before the money can be distributed. His wife and children in direct descent are all dead. He makes a will some time before his death in favour of the widow of one of his sons, and certain sums to his grandchildren. He, however, becomes bankrupt just previous to his death, and when the money left him by his brother comes to be distributed, his will is set aside, and his grandchildren are called upon to administer with the will attached to the letters. Two of the grandchildren (known to be abroad) cannot be found; their shares are consequently invested till they are traced. One (a married female) is now discovered to be dead—though alive at the time of distribution. Her husband had abandoned her some years previous to her death, and she died in a charity hospital. Is her husband entitled to this money? Or must it be distributed amongst her brothers and sisters living? All are decidedly against the husband, who, it is discovered, behaved very badly indeed.—X. Y. Z.

[52998.]—**Moon's Motion.**—I hope I shall not trouble you too much if I ask some further information about the moon's motion and her effect on the tides. I wish to know what effect would be produced by the moon's motion—which is very variable. If I take the N.A. for, say, 1855, the interval from new moon, Feb. 16th, to first quarter is 6 days 22h. 46m. 12s.; from first quarter to full moon, 8 days, 4h. 34m.; from full moon to last quarter, 7 days, 15h. 51m.; from last quarter to new moon again, 6 days, 14h. 45m. So it appears that the rate of the moon's motion is subject to considerable variation, for the first quarter is made in little more than 6 days, 22¾h. The second is only finished in 8 days, 4½h. In an old astronomy it is stated that the moon's absolute motion from her change to her first quarter is so much slower than the earth's that she falls about 240,000 miles behind her at her first quarter: that is, she falls back a space equal to her distance from the earth. From that time her motion is accelerated to her opposition when she is come up as far as the earth, having gained what she lost in her first quarter. From full to last quarter her motion continues accelerated, so as to be as far before the earth as she was behind it at her first quarter. The moon's motion is slower than the earth's from her third to her first quarter, and swifter than the earth's from her first to her third quarter. I scarcely understand what is meant by the expression that the moon's motion is "slower" and "swifter" than the earth's, as it is thus stated to be. However, this being the case, may I ask what would be the effect of the moon's variable motion on a body, such as the tides, as they follow the moon daily in her declination? It is also said the tides are sooner in the moon's first and third quarter, and keep back in the second and fourth. Why is this? Would a body on the earth following the moon's motion go to the east or come from the east? It seems at first sight that if the moon's motion is slower than the earth's, it should come from the east, and when swifter go to the east. The moon comes to the meridian so many minutes later every day. These minutes represent so many degrees, and I find that it is sometimes 10°, and sometimes 15°, or even more, in excess; but always later. Consequently, I fail to understand why it is said that the moon's motion is "slower" or "swifter" than the earth's.—George.

[52999.]—**Electro-Magnet.**—To Mr. J. Sprague.—In the issue of the "E. M." for Jan. 18, under the heading Electro-Magnets, paragraph 28, you describe an electro-magnet with only one helix. Would you kindly state whether the form will attract as powerfully as the ordinary horseshoe-shape with two helices? I have a number of small magnets to make, and if the one helix pattern is as powerful as the two helixes, it will save a lot of wire.—Amateur.

[53000.]—**Slide-Valve Motion.**—Will one of our kind readers please give me information as to how the valves of the L. & N.W. compound engines are worked? I am getting the patterns out for ½h.p. engine, and would like to apply it to the same. A slight sketch, if convenient, will greatly oblige.—A Mechanic.

[53001.]—**Cement Hearth.**—Can any of "ours" inform me of any method of whitening a cement hearth so that hot coals falling on it will not discolour it to any extent. Would like something that is not dusty. Is Asbestos paint any use?—Nemo.

[53002.]—**Strength of Beam.**—If a beam will support a load of four tons in the centre of a 6ft. span, what uniformly distributed load would it be safe to place on it over a 12ft. span? Does the safe weight decrease as the span increases, and in what proportion?—E. E. R.

[53003.]—**Soda and Alum.**—Will any chemical correspondent inform me what action takes place on mixing solutions of the above, and what is the deposit which is formed thereby?—J. H. S.

[53004.]—**Launch Engines.**—I shall be glad to know how to fix a pair of launch engines in a wooden boat, how to line out the position of the shafting. Also whether the process is the same for fixing engines in an iron boat? as, of course, it is easier to adjust the engines where fixed on wooden blocks.—F. Wallace.

[53005.]—**California.**—I shall be glad if any one can give me such information about California as is given in this week's Mechanic about Florida? My present intention is to go there to start fruit-growing; but I should like as much information as possible before fixing definitely.—J. M. M.

[53006.]—**Microscopical.**—Will Mr. Lewis Wright, "Monachus," or some other student of optics, explain what is "the usual system of converging lenses" used for showing the rings in crystals by polarised light, as referred to in the extract from *Jour.* R. Mic. Soc., given in "E.M.," p. 490? I have long wished to fit my microscope with an apparatus for this purpose, and shall be glad to be told how to do it. Further, how, or by what colour, are plates of selenite or mica (?)—giving, respectively, ¼ and $^{3}/_{4}$ wave retardation—to be identified? See "E. M.," p. 489.—Emeritus.

[53007.]—**Electric Gas Lighter.**—Can any of "ours" give instructions for recharging the battery used in above? Also particulars of construction.—Nemo.

[53008.]—**Legal.**—A deed of settlement is entered into on the marriage of A. and B. C., D., and E. are the trustees. It is desired by A. and B. to do away with the settlement, and discharge the trustees. The deed is in the hands of the solicitor who drew it—he being the adviser of D., one of the trustees—and he refuses to part with the deed, and evades even giving a copy of it to the solicitor of A. and B How can he be compelled to give up the deed, or a copy of it? What is the nature of the procedure required? C., the first trustee, is willing to assist. The solicitor of A. and B. does not like to take hostile steps against a townsman and fellow-practitioner.—U.

[53009.]—**Magneto-Electric Machine.**—I have one for medical purposes which has been put aside for some time, and now can get no shocks from it. The magnet is circular in form, and poles cut out in semicircular ends, between which an armature revolves, somewhat like Siemens'. On the axis of armature is the commutator. The reversion takes place when the two segments of iron portion of armature are opposite the poles of magnet. The connections are all clean and good. The large magnet is not very strong, and is 5½in. outside diam. The armature is wound longitudinally with very fine silk-covered wire, the ends being attached to the two semicircular portions of commutator. Will some one give me some assistance as to discovering cause?—W. H. H.

[53010.]—**Making Banjo.**—Can any reader kindly tell me of a method of making a drum for a banjo? I am pretty handy with my tools, and feel sure that I could make one, if some one would inform me of the best kind—American (with a back) or English (open)? The variety of wood used, how to bend it round, how to stretch the parchment?—P. A. I.

[53011.]—**Theiss Bridge.**—I should be pleased if any one would give me a section of the cylinders of the Theiss bridge at Szegedin, showing method of working, ingress and egress chambers, escapes and supply cocks, &c. Any information will oblige.—P. A. I.

[53012.]—**Escape of Steam.**—How many cubic feet of steam would escape into the open air from a 5-16in. circular pipe, the pressure-gauge on boiler being 35lb.? What is the formula?—Chas. Heard.

[53013.]—**Removing Colour from Fish Oil.**—Can any reader oblige me by giving a simple method of effecting this?—J. I. D.

[53014.]—**Cream in Condensed Milk.**—Some days ago I tried the First Swiss Brand condensed unsweetened milk, and found that after adding water the cream did not rise, and yet it is said no cream is abstracted from the milk previous to condensing. Will some one be kind enough to explain the mode of preparation, and say whether anything is added to the milk to prevent the cream rising?—Harrow.

[53015.] — **Expansion.** — Can anyone please answer me one or two questions on this point that I have asked before without getting any satisfactory reply? (1) If a gas is said to expand $\frac{1}{n}$ for each degree of heat, from 32° to 42° Fahr., does this mean that for each degree it expands $\frac{1}{n}$ of its bulk at 32°, or does it expand for every separate degree $\frac{1}{n}$ of its bulk at the temperature taken? Similarly, for expansion under barometrical pressure, is the increment equal in bulk at each 10th of an inch of mercury, say, from 26in. to 31in.? Or, is the increment for each 10th proportioned to its bulk at the point taken? (2) What is the law with liquids regarding this same question? (3) Can you give me the coefficient of expansion of sulphuric acid, glycerine, and petroleum respectively? Information on any of these points will much oblige.—Guido.

[53016.]—**Battery for Electric Light.**—I am about constructing a battery of 40 Bunsen cells for electric light, and should like to know what power light I ought to get from 40 cells? The size of carbons is 7 by 1½in. by 1in., zinc cylinders 6½ by 3in.; outer jars, 6 by 4in. inside measurement. The lamp I am going to use is the arc, with ½in. carbons; but please state what size you think best to obtain the best results from the number and size of cells given.—C. A. B.

[53017.]—**Electroplating.**—Would Mr. Lancaster kindly tell me the best method of connecting six quart bichromate cells (with Trouvé's solution) for electroplating? If joined up in multiple arc, would the E.M.F. of one cell be sufficient to deposit for three hours without giving the battery rest? Also tell me what current I might expect to get if joined up in this manner?—No Name.

[53018.]—**Convergent Lenses.**—Will some optical correspondent kindly give (in language that ordinary English mechanics can understand) a description of Nuremberg's polariscope and the convergent lenses referred to at p. 490? Perhaps Mr. Wenham will oblige, and give, at the same time, a diagram of a 1-12 dry micro.-objective, and one of a 1-12 water immersion, pointing out the difference in their construction, the position and foci of the flint and crown lenses of which they are built up.—D. T. K.

[53019.]—**Fixing Windows.**—Can any reader inform me of a good practical method of fitting the window sashes, especially those of the upper floors, in such a way that they can be readily taken out or reversed? My object in view is to enable windows to be easily cleaned without the cleaner having to get outside; also that sash-lines can be mended, or broken panes of glass repaired without necessitating the whole frame and beading having to be taken to pieces—to the great injury of the paint in a nicely-decorated room. An additional advantage would be gained if the plan adopted could, at same time, be utilised to tighten window-frames during bad weather in a house where the upper part is much exposed to sea air and south-westerly gales.—A. Lloyd.

[53020.]—**Who Discovered the Lunar Clefts?**—In Fontinelle's "Conversation on the Plurality of Worlds" the following passage occurs: "The illustrious M. Cassini, who has acquired a greater knowledge of the celestial bodies than any man in the world, discovered in the moon something which separates, then reunites, and afterwards loses itself in a cavity. We have reason to believe, from its appearance, that this is a river." I imagine that the Cassini referred to is John Dominic Cassini, the founder of the illustrious family of astronomers bearing this surname, who constructed a map of the moon in [illegible]. Can any of your readers inform me if they have seen in the works of J. D. Cassini, senr., a record of the observation to which Fontinelle refers. The passage can, it seems to me, be only understood to relate to something resembling a cleft or rill, though to Schroeter is always given the credit of discovering these remarkable objects. I am aware that Arago "Popular Astronomy," Vol. II. p. 257, Smyth and Grant's translation, refers to this passage in Fontinelle's "Conversations"; but he does not appear to have seen the original record on which it is founded.—Thos. Gwyn Elger.

[53021.]—**Confectionery.**—Will any of your readers inform me the description of apparatus used in confectionery for making sweets in the form of pills?—Wave.

[53022.]—**Black Colour for Cement.**—I am laying a cement floor at present, and want to colour it black. Could any reader inform me what the ingredients are to do so? I have tried lampblack; but it does not agree with the cement. Neither will engine ashes do alone.—A. W. [illegible]

[53023.] **Money Table.**—Could some reader of "ours" give me a table by which I could tell what I owe to a building society at any time I may wish to pay out—which is allowed by the society? I borrowed seven shares at £[illegible] each, at 5 per cent., on Feb. 13, 1873, and have paid from that date £[illegible] per month. How much should I have to pay in Feb., 1884, or at any other time to redeem my property?—[illegible]

[53024.]—**Wimshurst Influence Machine.**—I am constructing a Wimshurst solely on the instructions given in "ours." There are one or two little matters which I would like detailed—principally, the sectors and the method of cementing them to plates. I have made mine 2¼in. long, ¾in. at top, ½ at bottom, rounded at both ends. I intend cementing ¼in. from edge of plates. Will any one say if I am right? Also let me know what kind of cement I should use.—Very Much an Amateur.

[53025.]—**Varnish.**—Can any one suggest the best way to filter spirit varnish? Are there any filter presses in the market suitable for the purpose?—No. 3.

[53026.]—**Tempering Cooper's Tools.**—Will some reader inform me how electro-boracic steel is tempered in my trade (cooper)? Our principal cutting tools are made from it, and it is very rare now to get a tool tempered right (more frequently soft than hard).—Amateur.

[53027.]—**Cistern.**—Will some reader give me an answer to the following in plain figures? A cistern lined out with 5lb. sheet lead to the square foot, 6ft. 8in. long, 4ft. 5in. broad, 2ft. 6in. high. What will be the weight of the sheet lead, and the quantity of water the cistern will hold?—Durham.

CHESS.

All Communications for this department must be addressed to J. Pierce, Bryn Rhedyn, Llandwrog, Carnarvon.

PROBLEM DCCCLXXIV.—By J. Pierce.

NOTICES TO CORRESPONDENTS.

Correct Solutions to 872 from W. J. Francis, J. G. E. (Sittingbourne), Rev. W. Anderson (Old Romney); to 871 from W. J. Francis.

R. A. Bennett.—You have overlooked in 872 that Black B can check at Q sq on first move.

Game received with thanks from J. Jowett.

Jequirity Poisoning of Fowls.—As a continuation of their work on jequirity MM. Cornil and Berlioz have recently read before the Académie de Médecine a further contribution on the effect of the bacilli of jequirity on fowls. A single injection of ten to twenty drops of the infusion into the subcutaneous connective tissue of the breast produces a rapid poisoning, terminating in death, the chief symptom being copious diarrhœa. The liquid stools contain numbers of the bacilli. The skin becomes infiltrated with a clear liquid, which abounds in bacilli; the great pectoral muscle becomes voluminous, as happens after an injection containing the microbe of the cholera of fowls. Microscopical examination of the muscle shows transverse ruptures and necrobiosis of the muscle fibres, with infiltration of the connective tissue by fibrin and lymphatic cells, just as in the cholera of fowls. With an injection of a small quantity the fowls remain alive, though a local œdema, with damage of the neighbouring muscle, is produced, but immunity is acquired. A fresh injection into the peritoneal cavity seems to be partly eliminated by the previously induced local mischief. The lesions set up by the microbes continue to evolve apparently after the complete elimination of the micro-organisms.—*Lancet.*

ANSWERS TO CORRESPONDENT

⁂ All communications should be addressed to the E of the English Mechanic, *31, Tavistock-street, Co Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put dr ings for illustrations on separate pieces of paper. 2. titles to queries, and when answering queries put numbers as well as the titles of the queries to whi replies refer. 3. No charge is made for inserting le queries, or replies. 4. Letters or queries asking for dresses of manufacturers or correspondents, or wh tools or other articles can be purchased, or replies gi such information, cannot be inserted except as adver ments. 5. No question asking for educational or sci information is answered through the post. 6. Letters to correspondents, under cover to the Editor, are not warded, and the names of correspondents are not gi to inquirers.

⁂ Attention is especially drawn to hint No. 4. pace devoted to letters, queries, and replies is mea the general good, and it is not fair to occupy it with tions such as are indicated above, which are only of vidual interest, and which, if not advertisements in the selves, lead to replies which are. The "Sixpenny S Column" offers a cheap means of obtaining such inform tion, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand to Wednesday evening, Feb. 13, and unacknowledg elsewhere:—

AN AMERICAN TRIAL OF AN OTTO GAS-ENGINE.

AN elaborate series of experiments made at the Stevens Institute of Technology to determine not only the actual efficiency and economy of an Otto gas-engine, but also the extent and proportions of the losses met with in its ordinary operation, has been carried out by Messrs. M. Brooks and J. E. Steward. The capability of these gentlemen is vouched for by Prof. R. H. Thurston, who writes an introduction to their exhaustive paper, which appears in the current number of *Van Nostrand's Magazine*. Some earlier investigations, carried out by Prof. Thurston and his assistant, Mr. Cartwright, had given a fairly good idea of the causes of waste in the gas-engine; but the former thought the collection of further data desirable: hence the elaborate report made by Messrs. Brooks and Steward of no fewer than 20 trials of a 10 h.p. (indicated) Otto gas-engine. In Prof. Thurston's experiments, he found the consumption of water-gas to vary from 21·2 cubic feet per hour per horse power in engines of 6 to 7 i.h.p., to 24·5 cubic feet in engines of 2 h.p. or less. The friction of the engine varied from 40 per cent. of the power in the smaller to 20 per cent. in the larger engines, while the waste at the exhaust ranged from 12 per cent. of the total heat of combustion in the small engines to 24 per cent. in the large. The water jacket carried off from 45 to 55 per cent. of all the heat supplied by the combustion of the gas. Except that corrections will have to be made for the price of gas, the report of Messrs. Brooks and Steward will be found of considerable value in this country, for their twenty trials were made, so far as concerns one moiety, with varying powers, while the other half were made at full power, but with slight differences in the number of revolutions per minute. From the figures supplied by these trials, it appears that the total heat accounted for thermodynamically is 34 per cent. of the total quantity supplied by the combustion of the gas, consisting of the heat actually transformed into work and that expelled with the exhaust; the water-jacket, radiation, &c., account for the other 66 per cent. It follows, then, that if this loss can be materially reduced the gas-engine would at once take a far more prominent position than it has already done; for its convenience, safety, and economy all combine even now to render it *the* motor for small power-users, especially in cases where the power is required intermittently. The engine tested at the Stevens Institute has a stroke of 14in., and the diameter of the piston is 8½in. It has two flywheels, weighing together 1,650lb., and a pulley 30in. in diameter was used in connection with a Prony brake. Both gas and air were taken from rubber bags after passing through meters, and even the quantity of water was measured (as well as its temperature before entering and after leaving the jacket), though that is not material to the experiment, as the same water is used over and over again. A pyrometer in the exhaust gave the temperature of the discharged gases; a Tabor indicator was mounted directly on the cover of the exhaust passage, and a speed counter was attached to the link moving the slide-valve. We mention these details to show that the trial was carried out thoroughly; but our space will not enable us to reproduce the elaborate table in which the results of the tests are set out. It must suffice to notice the chief points. The gas used in the experiments was that obtained from the street mains of Hoboken, New Jersey, which, besides costing 10s. per 1,000 cubic feet, is, it seems, of rather poor quality, so much so that the reporters make a special note in which they show that 21 cubic feet of average good quality illuminating gas is sufficient to develop one horse-power per hour in the Otto engine. The gas consumption with varying power was found to be nearly constant per i.h.p., but of necessity varied with the effective horse-power, because the friction increases in proportion to the useful work. The figures given under these heads show the value of the governor, which cuts off gas whenever there is an excess of speed, and thus insures economy in consumption when the engine is not required to exert its full power. The experiments to determine the ratio of air to gas gave about seven of air to one of gas, and, making allowance for the poor quality of Hoboken gas, that indicates that the ratio of 10 to 1 usually assigned must be slightly in error, due no doubt to the method adopted in ascertaining the ratio —viz., by taking the volume of the piston displacement less the measured amount of gas. The ratio obtained at the Stevens Institute is that of actual measurement, and some tests were made to show the effect of increasing the proportion of air, the result being that it is found to be false economy to throttle the gas supply, as the consumption increases per effective horse-power, though little difference is noted per i.h.p. From the figures given in the table it appears that the amount of heat carried off by the water is about half the total heat given by the combustion of the gas; but when the cylinder is kept cool by a plentiful supply the quantity of heat carried away appears to be greater than when less water is used and the cylinder is allowed to become warmer. When a comparison is made with the indicated or the actual work it is found that no advantage is to be obtained by using the minimum quantity of water, and the authors suggest, as a probable explanation, that much more heat is lost by direct radiation when the cylinder is warm than when it is cool. Messrs. Brooks and Steward have rendered their report complete by entering into an explanation of the theory, taking the thermal constants of the gas, the air necessary for complete combustion, specific heats, and a number of indicator diagrams into consideration. As the latter fail to account for 40 per cent. of the total heat, and as it is certain that the heat carried away by the water-jacket comes from the gas, it becomes of some importance to learn exactly what occurs. According to Messrs. Brooks and Steward, it is a well-established fact that heat decomposes chemical compounds. Carbonic acid, for instance, is separated into carbonic oxide and oxygen at a comparatively low temperature. At the temperature reached in a gas-engine after an explosion it is almost certain that this action of dissociation occurs, and prevents the complete combustion of the gas taking place instantly. As the temperature decreases from expansion further burning ensues; and thus they say it is quite possible that the gas is not fully burned until after the opening of the exhaust valve. This view is certainly worthy of attention, as it serves to point out the direction in which further improvement should take place. From these trials it may be stated that the efficiency of a gas-engine of the Otto pattern is 18 per cent. indicated of the total heat of combustion, and 14½ per cent. actual useful work. The best steam-engines utilise only 10 per cent. of the heat-units of the coal, and small engines rarely exceed 5 per cent.; so that it seems clear that the gas-engine is by far the more perfect heat-engine. An estimate of the running cost and interest on capital of a gas, steam, and hot-air engine in America gives the relative positions as steam, hot-air, gas; but the position of the latter is due entirely to the high cost of coal-gas in that country (10s. per 1,000 cubic feet), and, as Prof. Thurston says, "even now the gas-engine has found innumerable applications." As its running cost is reduced by the use of special gases, and its economy is increased by improvements in design and construction, the field of its usefulness will, he thinks, indefinitely widen. In this connection it may be mentioned that the Dowson water-gas, as used at Messrs. Crossley's works, gives one i.h.p. an hour on a consumption of 1·4lb. of anthracite—one attendant being sufficient to look after Dowson gas apparatus capable of supplying 300 i.h.p. The only steam in their large works is that found absolutely necessary in working steam-hammers.

REVIEWS.

The Art of Soap-making. By ALEXANDER WATT. London: Crosby Lockwood and Co.

IN his preface, Mr. Watt says he has, in compiling this book, endeavoured to fill a void in English technical literature, for, so far as he is aware, the art of soap-making has been left without a textbook adapted to the wants of the many. We believe that is to a certain extent true, although there are many cyclopædias, &c., which contain the elements of the art, and several translations of works by foreign authors, from which latter Mr. Watt has drawn much of his information. The art of soap-making is to be found in those special blue-books issued by the Patent Office; but to understand many of them one must be already an expert, whereas it is some handbook that would give the practical details of routine, manufacture, and recipes of known value that has been wanted. We think we may say that Mr. Watt has supplied the want, although it must not be forgotten that soap-making, to be commercially successful, requires the services of a competent chemist who is also familiar with the details of the factory. Chevreul, the distinguished and venerable French chemist, was one of the first to clearly explain the nature of the reactions when fatty substances are treated with boiling solutions of caustic alkali; but it was not until keen competition made itself felt that soap-making was elevated into an art. In his first chapter Mr. Watt explains saponification, giving Chevreul's theory, and an epitome of Liebig's researches, with some remarks on the great importance to the soap-maker of a knowledge of alkalimetry. The succeeding chapters take us at once to a brief description of the works, and the materials employed therein, and Chapter V. treats on the manufacture of hard soaps, that is those made by a combination of soda and water with fatty matters; soft soaps being combinations of potash with certain kinds of oil, mostly those of inferior quality, as horse-oil, fish-oil, &c. Castile soap is properly made from a pure olive oil of the third quality—that is, the oil obtained by boiling the residuum of the presses in water; while London mottled is a combination of kitchen stuff or any cheap fat with the crude soda known as black ash, the impurities in which impart the mottled or marbled strike. The abolition of the Excise duty on soap gave an impetus to invention, and accordingly we find in this book a chapter on cheapened soaps, in which Dr. Normandy's process is described, and those processes which utilise the silicates of soda and potash. These silicates and fuller's earth can scarcely be considered adulterants, as they possess detergent properties themselves; but the silicate soaps are at any rate not suited for toilet purposes—though [illegible]

[illegible]

[illegible] is a practical [illegible] as a useful [illegible] and a valuable [illegible] landlords. It [illegible] various kinds of [illegible] apparently in- [illegible] necessary, from [illegible] boxes.—*T*[illegible]

[illegible] *Masonry*, by [illegible] Baillière, Tindall [illegible] of what is known [illegible] *drawing*. It is [illegible] and Sons, are fairly [illegible] designs, which [illegible] amateur carvers, and [illegible]

THE DIALYTE TELES

By W. Bre

MY attention having been [illegible] articles on the telescope [illegible] years ago in *Design and Work* [illegible] that some very good [illegible] given. The writer recommends [illegible] thickness 21 or 22 Birmingh [illegible] inside diameter, and [illegible] lens is a 5in., giving 4 [illegible] "ultimate" focus [illegible] are as follows:

[illegible] crown object [illegible] apertur

[illegible] convex crown, radius...
[illegible] concave (Chance's heavy flint [illegible]
[illegible] sides towards each other [illegible]
Distance of correctors from o.g., about [illegible]

I cannot understand how a 20in. plan [illegible] be used for this combination [illegible] focus would be something und [illegible] length. Perhaps it is a misprint [illegible] which seems much nearer the focus gi [illegible] would give a length of nearly 5ft., which [illegible] certainly be lengthened to 6ft. by the [illegible] the correctors.

Inside the large tube is a short [illegible] 12in. long, fitting very closely; this is fla [illegible] the interior side at one end, and thro [illegible] circular aperture thus formed a short br [illegible] having an outside flange, is passed. Fo [illegible] unite the adjacent flanges, thus servi [illegible] means of regulating the axial adjustme [illegible] corrector tube is double, consisting of [illegible] tube containing the flint lens, sliding [illegible] within an outer one containing the cr [illegible] This outer tube slides accurately thr [illegible] short brass tube just mentioned: therefore [illegible] the correctors may approach to or rec [illegible] the object lens by moving the double tu [illegible] short one; or, secondly, the correctors [illegible] separated from each other by withdra [illegible] inner part of the double tube. The first [illegible] serves to correct the chromatic error; the [illegible] to correct the spheric aberration. [illegible] some means must be provided to preve [illegible] adjustments being upset by any move [illegible] telescope. I do not see this point notic [illegible] writer of the articles.

After the places of the lenses have been [illegible] determined, the mounting must be put [illegible] for fine adjustment; but, before this can [illegible] the centres of the parts must be [illegible] aligned. To do this, the writer recomme [illegible] the lenses to be removed, and three [illegible] right-angled cross wires to be prepared [illegible] first pair to be placed across the object e [illegible] the second and third pairs at each end tubes carrying the crown and flint hen by placing the eye at the hole in ce, the corrector tube must be shifted the intersections are brought in a line. made in the large tube to allow access rector fittings.

tly two movements must be provided e attachment of the corrector mount to ar. For, first, the centre of the corrector y be eccentric to that of the large tube; ondly, the centre lines of the two tubes athwart each other. The second error remedied by tilting the flange of the rass tube, that is by inserting packing n it and its neighbour, in the proper place g the axes to parallelism. If the centres n eccentric, the brass tube must be moved ly until the error is removed. This itates the screw-holes in the flange being nough to allow some displacement.

n afraid this centring process will be found ost tedious and irksome job connected with alyte. It will certainly be no easy matter at a delicate adjustment by shifting the s in the narrow confined space between the ubes, as they are anything but get-at-able at position. I am of opinion the following is more practicable. If the large tube is ght and parallel it is certainly better. ure a brass tube which will carry the double of the correctors. At each end of this fix wo circular discs or flanges; mount the tube true mandrel and turn up each end exactly e to fit into the large tube. But, if the trues of the large tube cannot be depended on, I do see a simpler or easier plan than the following. rn the discs less in diameter than the inside the tube. Next, having roughly determined place of the correctors, fix two stout brass ngs on the outside of the large tube, so that ch shall be exactly over the flanges inside. ut four screws equally apart through each ring. et these screws be fairly thick, with coned oints; they are best of steel, without heads, with saw-cut for the screwdriver through their ubstance; they will then be less likely to catch r get disarranged. Screw down lightly at first, o as just to dint the flanges; take out the mount, nd deepen these marks with a centre punch. Then, by means of these screws, the correctors may be adjusted to any degree of nicety, and they serve also to keep the mount in position.

With regard to the process of correction, the writer observes: — "The eyepiece must be inserted in its place, and the test object kept in the *centre of field* of view. For the chromatic correction, cleanly cut red and blue or violet letters, placed in a bright light on a white ground, about 50 or 60 yards distance, make an excellent guide.

"For the spherical aberration, a finely-lined watch dial, placed in a strong light at about the same distance, and viewed alternately by the centre and edge of the o.g.,' forms a good test. A slight over-correction in each case will afford finer definition with these instruments than the opposite error. The equal appearance of the enlarged star disc, when the eyepiece is moved to equal distances within and without the focus is not to be relied upon as a test for a dialyte telescope."

The correction of the oblique chromatism "may be brought about by drawing out the tube containing the field lens of the eyepiece, until an object is found to cross the field of view without any disagreeable display of colour.

"The eyepiece used should be of the Huyghenian type, but the lenses should have their respective foci in the proportion of 3½ or 4 to 1.

"Errors of centring will show themselves in an unequally coloured field, and, if the objective is not square to the axis, the diffraction rings will be thrown eccentric with the image."

The writer assigns the following reasons why it is preferable to use a plano-convex object lens:—"For the perfect correction of the *spherical aberration*, the compound lens must be so calculated that it shall, when in contact, somewhat *over-correct* the aberration of the object lens. A perfect balance may then readily be brought about by slightly separating the lenses." Hence he advocates the use of a plano-convex, because its error is greater than that of a double convex, and it may also be increased by reversing the lens.

To find the foci of the correctors, the same rule is used as I have already explained. But, it may be remarked that this rule is not exactly correct unless each corrector has the same focus. This cannot be so when the same curves are used for each lens. It is the ordinary plan to make them alike; hence, we can be certain that the negative error is in excess — chromatically, *always* — spherically, *sometimes* — depending on how the curves are arranged. The heavier the flint, the more will its refraction and dispersion preponderate.

To find the diameter of the correctors the following rule is given.

$$x = \frac{d\,(A-a)}{F} + a$$

"Where x represents the diameter (that is, the clear effective aperture) of the correcting lenses; d the distance of their centres from the focus of the object lens; A, the effective aperture of the object lens; F, its principal focus; and a, the diameter of the field lens of the lowest power eyepiece it is proposed to use."

If d is half the focal distance F, then $x = \frac{1}{2}(A + a)$; or if one-third, $x = \frac{1}{3}(A + 2a)$. Those who contemplate making a dialyte, would do well to read the articles in the journal I have named.* They are excellent in many respects, though I think the writer's plan of a corrector mount may be much improved. Also it is probable that a series of circular cards, perforated with a small hole at the centre might be more readily applied in the alignment of centres than three systems of cross wires. A bright light might be placed so as to be visible at the eye-cap through the hole at the centre of the object end; then the corrector tube would have to be so placed as not to interrupt the line of vision.

The writer mentions a dialyte made by Professor Wilson, of Glasgow, in 1828, which had the following dimensions:—

Crown glass index, 1·53; dispersive power, ·032.

Flint glass index, 1·58; dispersive power, ·052.

Plano-convex object lens, 4in. aperture, 48in. focus, mounted in a tube 6ft. long, with plane side outwards.

Correctors, plano-convex and plano-concave, 2in. aperture, and each curved to a radius of 3·71, and placed 26in. from the object lens.

I have been favoured with an account of a dialyte made by a gentleman, who, I presume, has, to a certain extent followed the directions given in the papers just quoted. It appears to be of the same dimensions, and of glass of a similar quality. The account is as follows:—

"The o.g. (5in. aperture) was made out of a piece of carefully selected plate-glass, plano-convex, radius 30in., focus 60in. The correctors, 2½in. diameter, were made from a pair of Swiss discs; the density of the flint being 3·67, almost the same as Chance's 'dense flint,' and the density of the crown about the same as Chance's, i.e., 2·55. The crown lens was plano-convex, 5in. radius; the flint, plano-concave, also 5in. radius. The o.g. was mounted in brass cell, end and cap. The correctors in two tubes, one sliding within the other, and these tubes together sliding in a short tube with two brass rings, one at each end, just fitting tightly in the main tube of the telescope. This main tube was of zinc covered with American cloth; the polished brass ends gave it a satisfactory appearance. It had a door in the proper place for introducing the hand to adjust the correctors. The eyepiece was made so that the field lens could be separated considerably from the eye lens, and rack motion to focus was provided.

"The correctors and eyepiece were adjusted together in the tube for colour and spherical aberration on a watch dial at about 100 yards distance, and carefully centred. All the adjustments being correct, it was found that the colour was well corrected; and, to correct the spherical aberration, the lenses of the correctors had to be very slightly separated. The definition on the moon, planets, and stars was very fair indeed when the object was kept in the centre of the field."

In concluding my notice of the dialyte, I think it will be admitted that it is not advisable to resort to this form for apertures less than 4½in. or 5in.; and, even in this case, if the amateur has to get nearly all his work done for him to order, it would probably be more satisfactory to buy a less instument on the ordinary construction. If he can grind his own lenses, or more especially if he can do his own fitting and mounting, then the cost of the instrument should not run into a large sum. It is rather remarkable that no practical optician advertises dialyte lenses for sale. A 5in. plate, plano-convex, 30in. radius, and two 2½in. convex and concave planos, 5in. radius, are very simple forms; and, if one may judge from the prices of other similar lenses, the lot ought to be obtainable for under 30s. Looking over some back volumes of this journal, I find 5in. single object lens and eyepiece advertised at 10s. 6d., and most certainly the pair of correctors ought to be had for 12s. or 15s., for glass of ordinary quality. Probably the focal length of such single-object lenses as I have alluded to would be too great to turn into a convenient dialyte, but a shorter focus should not cause extra expense.

PRACTICAL NOTES ON PLUMBING.—XCIV.*

By P. J. Davies, H.M.A.S.P., &c.

(*Continued from page* 508.)

The Theory of the Circulation of Hot Water through Pipes, &c.

IT would appear (from the preceding facts) plain that the colder the water the heavier it will be, while the lighter and warmer the particles will rise to the surface; but even in this there is a limit, which can only go down to 40° F., and from this point down to 32° F., when the molecules of water undergo a very remarkable change. Between the above degrees there is no contraction nor expansion, therefore it, bulk for bulk, does not become heavier nor lighter; but we are surprised to find its bulk increase when the degree of heat is below 32° F., when it crystallises into ice, and this expansion goes on in strict accordance to each degree of cold below the 32°, hence the reason why leaden and other pipes burst in times of frost. Of course my readers have seen ice floating on the surface of water, which will prove the above assertions in the most conclusive manner.

From the above it is plain that the circulation of hot water is brought about owing to the difference in the weight of the water at different points, caused simply by the expansion and contraction of the water itself; therefore, if the source of heat be permanent, the particles are rapidly brought into action, and the particles in a vertical tube soon become heated, and by their expansion must exert a pressure on all parts of the pipes, branches included. Now this, together with the levity of the water in the boiler, establishes a current, when the cold water from the coils, branches, &c., commences to flow in the direction of the boiler, and thus supplying the heavy or colder water continually, which, of course, takes the place of the lighter particles, known as hot water. To find the force with which the colder water runs towards the boiler, you must know the specific gravities of the water in the flow and return pipes, the flow being the ascending, and the return the descending; the difference between them will be the motive power, or the effective pressure. You can arrive at this point by ascertaining the temperature of the water in the return pipe and boiler, or flow pipe. If the difference in heat is only a few degrees, of course the difference in the speed of circulation of the water will be accordingly; say it is only four or five degrees, which is very small, but quite sufficient in a well-arranged system to maintain constant circulation. Let us assume that we have 8° of heat in our boiler B (see Fig. 438, A), the return pipe is standing at 180° and the flow to be 188°. Let the top of the flow pipe at F be, say, 18° above the top of the return R; the difference in weight will be about one-third of an ounce on the square inch, and this will be the amount of motive power obtained for the circulation, no matter what may be the length of pipes attached to the apparatus; and should there be, say, 50 yards of 4in. pipe, which will contain 80 gallons of water, with a 15-gallon boiler, you will then have 95 gallons, or 950lb. weight, kept in continual motion by the 8° of heat, or one-third of an ounce pressure.

Of course, the size of pipes will make a wide difference in the motive power, which increases with the size of the pipes; thus, in a 4in. pipe you will get four times as much as in a 2in., and so on, but, as the resistance increases equally with the power, the actual working effect is precisely the same in all sized pipes.

---

* They appear at pages 292, 369, and 450, Vol. V., 1878.

* From the *Building News*. All rights reserved.

Again, the motive power can be increased by allowing the water to cool down before it gets back to the boiler, either by increasing the height of the flow and return pipes, or by doubling the difference of the temperature between flow and return, or, of course, an extra power can be obtained by doubling the difference of the temperature between the return and flow pipes, when the same increase of power is obtained as by the doubling of the vertical heights; or by trebling the vertical height of the flow and return pipes the same effect is produced as by trebling the difference in the temperature of the water.

A difference in the motive power is also made by diminishing the diameter of the pipe in such a manner that a longer amount of surface will be exposed, and in proportion to the amount of water within this, of course, allows more cooling surface, and consequently the return pipes can give off more heat in a given time, thus making the return water denser, and consequently quicker in action. Of course, when you do this you have more friction, which will be readily understood from the following:

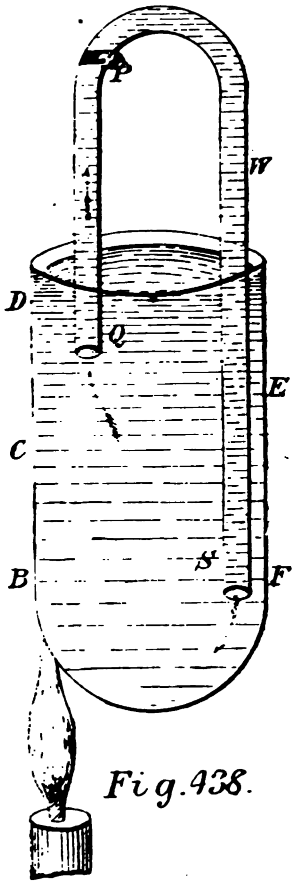

Fig. 438.

It is certain that the sides of the pipes greatly retard the flow of water, therefore a considerable deduction must be made, in some cases to the enormous extent of 80 per cent. In small pipes there is a greater amount of friction than in larger ones, owing to the relative amount of surfaces; besides, this small pipes cool quicker than larger ones, and thus the velocity is increased, as also is the friction, so that supposing we have a 4in. pipe, the amount of friction is, say, 1, in a 2in. there is twice as much, and in a 1in. four times as much as in a 4in., and you should also know that by increasing the velocity, so in proportion will be the friction nearly as the square of the velocity. It should also be known that in all hot-water apparatus the speed of circulation varies according to circumstances, therefore it is difficult to calculate; one thing is certain, that the velocity in all hot-water pipes is quickest in their centres.

The following is an easy method for estimating the velocity of hot water through pipes. Take an inverted siphon, Fig. 438, B, and place one inch of mercury in one leg, as at B G, and water in the other, as at A B; it will be found that the inch of mercury, B G, will balance 13½in. of water at A B, thus proving that the difference of the specific gravity is 13½ to 1. But suppose you use oil instead of mercury, then the water, bulk for bulk, will be the heaviest, and a column of 18in. of water will balance 2 columns of 20in. of oil; now suppose we have a turned off stopcock at X, and then put oil in one side of the siphon and water in the other, so that each fluid will stand at one level. Now suddenly open the stopcock, and you will find the oil to be forced upwards with equal velocity to that of a solid body falling by gravity through a space equal to the additional height which the lighter body would occupy in the siphon. Seeing that the relative weights of oil and water are as 9 is to 10, the oil must by the water be forced upwards with a velocity equal to that which a falling body would acquire in falling through one inch of space, which is equal to a velocity of 138ft. per minute, therefore you must estimate the speed of water in a hot-water pipe by the above rule.

Now, suppose your flow and return pipe columns to be 10ft. high, and your flow pipe to be 8 degrees hotter than the return, the hottest column of water will stand at ·331 of an inch higher than the colder, or there will be rather more than $\frac{3}{10}$th of an inch the difference in the height of the two standing columns, which will give a velocity of 79·2ft. per minute; or if the height be only 5ft. and the temperature as above, then the velocity will be 55·2ft. per minute, showing that the height of the two water columns, viz. 5ft. and 10ft., make a wide difference in the velocity of the flowing water. We will suppose the above temperature to be now doubled, viz 16°, and the height of flow and return to be 5ft. Now, that being so, the velocity will be 79·2ft. per minute, and so on proportionately.

Now that you thoroughly understand the principle of the circulation of the particles of water through pipes, &c., all the other work will be simple. You will find that the fittings described and illustrated will, after what I shall write, be A B C to you, more especially as I intend to explain them in the simplest manner possible.

(*To be continued.*)

COMMON LATHE TOOLS.—I.

BY the kind permission of the Editor, I am enabled to expand the articles on "Tools for a Cheap Lathe," as suggested by "West Bromwich" (letter 22274), into a more pretentious, and, as I think, more widely useful series on wood-working tools in general. This subject—interesting to all who, without having had a mechanical training, occupy some of their leisure hours with mechanical pursuits—I propose to divide into the two heads of—

I. Common lathe tools.
II. Common wood-working tools.

The workman gains his knowledge of tools by experience; the apprentice can always get his foreman or a fellow-workman to purchase his first set; but the amateur is entirely at the mercy of the shopkeeper, who often knows as little of the matter as his customer, and, even if he gets a good article, the chances are that he renders it unfit for use within a week through bad grinding or sharpening. I think, therefore, I shall not be disappointed if I assume that a few practical hints on the above-named subjects, embodying the experience of some 20 years in the workshop will prove interesting to a large section of our readers.

Common lathe tools may be few or many, according to the requirements of their owner, and tools for wood working or for metal working may predominate, according to taste. A workman is always adding to his stock of tools, until by-and-by he almost insensibly finds himself in possession of a very varied assortment, each member of which has a special use and a special history. From among my own lathe tools I will select and describe those which I consider either absolutely essential or of very general adaptability, and all the rest beside are merely modifications of these few and simple types.

Once for all, let me say that excellence in the production of plain turned work, whether of wood or metal, does not necessarily follow from the possession of a large quantity of tools, but depends entirely upon skill in their manipulation. In the hands of a professional woodturner a simple gouge is a marvellous tool, producing hollows, ogee's, and mouldings of various shapes with swift dexterity, aided only by the chisel where sharp corners are concerned. Those who handle the gouge with confidence and skill can turn out their work quicker, cleaner, and better than those who, dreading a disastrous "kick" or "catch," scrape away cautiously with round nose and chisel and diamond point. Therefore plenty of practice with the gouge is essential to the acquirement of a perfect command of the tool, and he who has acquired this mastery is, to a very great extent, independent of the rest.

The chief tools therefore required for wood turnery are plain gouges and chisels. An inch gouge, that is one an inch wide, is the largest that can well be used with a light treadle lathe, and to use that effectively means hard leg work. A ½in., ⅜in., or ¼in. will be more generally useful by far. The gouges should be well rounded in grinding Fig. 1, so that the point, and not the corners, shall be used for cutting, and they, in common with most of the other tools should be furnished with long handles—of which more presently.

In turning straight stuff, either between centres or on the face plate, the gouge may be held flat on its back without any danger of its catching in the wood; but, in turning mouldings and in boring holes with the cup chuck, the tool must be held *sideways*, and the corner of the gouge which is lowest, or, rather, speaking more correctly, some portion of that half of the gouge which is lowest, is the one that will be used for cutting, the higher corner being carefully kept away from the revolving wood to prevent a catch. Even, however, in rapidly roughing down plain wood surfaces, it is advantageous to handle the gouge in this fashion, using both sides alternately, since it cuts the wood quicker, cleaner, and with less friction than when used on the flat. Many amateurs become disheartened in their first attempts at turning, because of the difficulty of guiding and controlling the gouge. This is a lesson only to be learned by practice. The great thing is to *feel* the work. Thus, if turning down a moulding or, say, the ball on the end of a curtain pole, from circumference towards centre, there is the centrifugal force very sensibly tending to throw the gouge outwards, and this, of course, is the force which must be resisted. The point of the gouge, or a portion just below the point, will be used, as offering least friction, *and it* must be grasped *very firmly*. In turning a flat surface, no such force exists, and the gouge may *be held* indifferently in any position and comparatively slack. Always the end of the gouge handle is held in the right hand, while the three last fingers of the left grasp the lower portion of the gouge itself. The requisite guidance is imparted to the tool by the thumb of the left hand, while the opposite forefinger passes underneath the rest, in oppostion to the thumb, thus gripping the tool as in a vice (Fig 19). Lastly keep the rest close to the work. If you have a wide space, you get too much leverage on the overhanging portion of the tool, and may catch and break your tool. The big gouges are stout enough to stand rough work safely; but the ¼in. gouge is a more delicate tool, and should not be used at all for roughing down stuff in the lathe, except it be of small diameter. These remarks may appear slight, but they really embody about all that can be said on the subject. Let the young aspirant bear in mind each direction, down to the very minutest, and he will find, when by much practice he has gained expertness in the use of the gouge, that all essential hints have been comprised in these few words.

Shopkeepers are always ready to "warrant" the tools of a respectable manufacturer—that is, if found useless on trial, they engage to exchange them, sending the bad articles back to the manufacturer. But sometimes, in the case of broken tools, they will dispute the justice of the claim made by the purchaser. The tool may have been broken by the purchaser's carelessness, and the only way in which the latter can prove his claim to have the article exchanged is by showing the presence of a flaw in the broken part. If, when the tool breaks, a dark spot (Fig. 2) is seen to occupy a portion of the line of fracture, that is a "flaw," or crack, and is quite sufficient to account for the breakage, and to condemn the tool. The dark spot is simply the film of rust which has formed over the old line of fracture. It should be taken back while the new fracture is fresh and clean, and easily distinguishable from the old.

A gouge for soft wood is generally ground at a long angle, similar to that shown in Fig. 3;

Fig. 1.

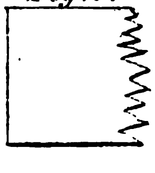

Fig. 17.

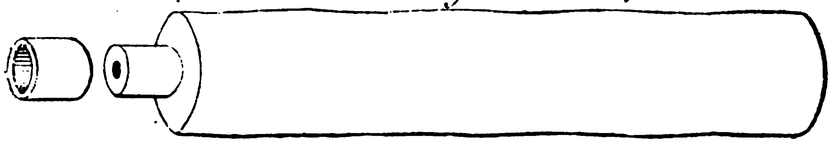

Fig. 18.

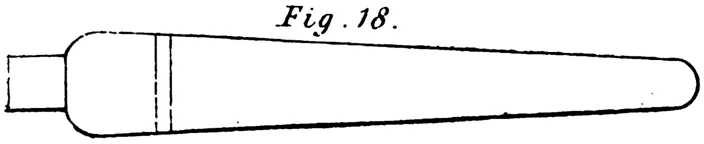

Fig. 9.

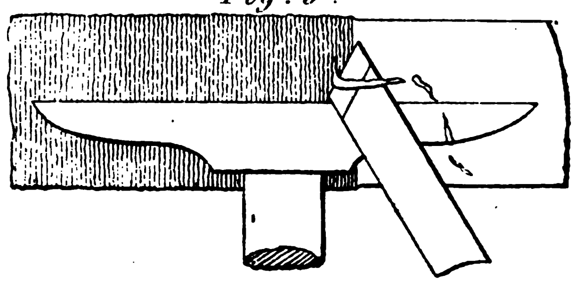

but for hard wood it may be a trifle less. But practically the same gouges are used indiscriminately for both woods, and the angle is always being rendered more obtuse by the process of sharpening. When newly ground the angle in the figure will be a good one. Prices of gouges —¼in. 7d., ⅜in. 8d., ½in. 9d , 1in. 1s. 3d.*

For side chisels we may select a large one, 1in., or 1¼in., and a ½in. and ¼in. And, by the way, though I mention these, a beginning may be made with one gouge and one chisel, say, a ½in. in each case, the others being added as required.

Grind the chisels to an angle of about 20deg. (Fig. 4). It should not be less—else they are liable to kick, and they should be kept thin and sharp (Fig. 5) for cutting down end grain with facility. If thick (Fig. 6) they "wobble" when cutting down across grain, with the result of leaving the work uneven (Fig. 7).

In grinding, some impart a slight amount of rounding to the cutting edge (Fig. 8). When turning, cut near the obtuse-angled end (Fig. 9), for if you get near to the opposite end, and slacken your grasp for a moment, the acute-angled corner will surely catch, and produce woful consequences. It is well to practise this side turning in preference to scraping, because the oblique cut is more like the action of a plane, and leaves the surface of the wood cleaner than does the tearing action of the scraping chisel. Yet two or three firmer chisels, say, 1½in, ¾in., and ⅜in., for truing up wooden face-chucks, and pieces of work of large diameter, and for recessing grooves, may be added with advantage. Prices of turning chisels—¼in. 6d., ½in. 7d., 1in. 11d.

Fig. 10 shows a round-nose tool, necessary in many instances where mouldings have to be finished, and indispensable also to the pattern-maker; ¾in., ½in., and ¼in. will be usful sizes. Of course these can only be used as scraping tools.

Side tools, Figs. 11 and 12, and diamond points, or parting tools, Fig. 13, are for turning, or rather finishing, the internal portions of rings (Fig. 14) or edges (Fig. 15) either inner or outer, which could not be got at by tools having less bevel. These, as well as the round-nosed tools, can be purchased; but they can be readily made, and will be quite as serviceable as the purchased ones, from worn out fine-cut flat files of different sizes. Grind off the greater portion of the cuts from their faces, and grind also the points to the required bevel or curve, as the case may be, and these will make excellent turning tools. You will be able to afford a greater variety by this means than if every tool had to be purchased. Always manage to utilise the old files in some way or another. Scrapers, screwdrivers, metal-turning tools, and I hardly know what besides, can be made from old files.

When purchased, tools are without handles, and though the ironmonger will supply you with the latter at about 2d. each, they may just as well be made as bought. Get some hard wood, almost any common wood, oak, ash, beech, birch, apple tree, &c., and saw into strips, some 11in. or 12in. long by 1½ square for the gouges and chisels, and others 8in. or 9in. long by 1½in. square for the scraping tools. Chop off the edges, start centres in ends with a gimlet, and run a cut in at one end with a tenon saw for the fork chuck. Get some brass tubing, ½in., ⅝in., ¾in. for different-sized tools, and cut off in lengths for ferruling. The neatest way to cut it off is this:—Say it is ½in. tubing. Get a piece of hard wood, not too long, say 5in. or 6in., and turn down to ½in., so that the tubing can be driven tightly over it by tapping with the hammer. When thus driven on, re-chuck the wood in the lathe, and cut off the ferrules with the point of a side chisel, or of a diamond point (Fig. 16). Tap out the wooden mandrel, file the burr from the inside of the ferrules, after which they are ready to go on their handles. Turn down one end of the wood intended for the handle—that end nearest the poppet—with calipers set to the inside diameter of the ferrule (Fig. 17), and drive the wood into the ferrule tight, opening the jaws of the vice wide enough for the edges of the ferrule to rest upon while doing so. Then replace in lathe and turn to shape, which may be either that of Fig. 18 or that of Fig 1, the latter being, in my opinion, preferable, as affording a larger grip for the hand. Bore the hole for the tool either with a gimlet or brace and bit, as straight as may be, sighting down gimlet and handle from time to time while boring. Open the hole out at the top with a taper shell bit, until the tool will drop in to within ¾in. or 1in. of its proper position, when the handle must be driven on over the shank with a hammer or mallet, holding the tool in a vice or against a block of hard wood while doing so. A couple of coats of shellac varnish given to the handles will improve their appearance and keep them clean.

Turning tools loose their edges very rapidly, and a quick fretting stone should be used for restoring them. A Charnley Forest stone (my favourite for ordinary tools) is hardly coarse enough for turning gouges. It may be used for the chisels, which require a finer edge; but for gouges a Grecian or a Washita stone is quicker in its action, or, even as I have sometimes seen, a piece of common slate will serve the purpose. Another reason why a special stone should be kept for the gouges is that they rapidly groove it out, and so render it useless for chisels and other tools having straight cutting edges. A slip of Charnley Forest will do for fretting the hollow portion of the gouge. Even that is not necessary when the tool is roughing down, since the revolving wood itself will knock off immediately the "burr" or "wire edge," which has been produced by sharpening the bevelled face.

The general subject of the grinding and sharpening of edge tools will, I think, be treated in a more connected and comprehensive fashion in a chapter specially devoted to it, than by sundry isolated remarks having no relation the one to the other. This I propose to do towards the conclusion of these articles.

NEW WATERPROOFING COMPOUNDS.

AMONGST new waterproofing compounds recently introduced, we notice the invention of Mr. W. Burnham, of Chicago, which has been patented in this country, and which is based on the peculiar properties of the sap of the mangrove-tree, known in the States of Columbia as Cativo. Mr. Burnham has discovered that, by combining this sap with caoutchouc in variable proportions, he is enabled to produce permanently elastic waterproof compounds. These compounds are capable of being made into waterproof varnishes by the use of the solvents and additional ingredients ordinarily employed in making so-called indiarubber or caoutchouc varnishes, and are also capable of conversion into products of greater or less hardness by the ordinary process of vulcanisation, either with or without the addition of the whiting, white lead, or other ingredients usually introduced into caoutchouc compounds. The so-called "cativo" is semi-solid at the ordinary temperature of the atmosphere, but becomes fluid at about 130° Fahrenheit. In preparing this material to serve as the base of the improved compound, it is preferably raised to a temperature slightly above that of boiling water for the purpose of diminishing the strength of its natural odour, and is then strained through a bag-filter to separate it from insoluble impurities. When strained and purified it exhibits a clear reddish-brown colour. In this condition it is mixed with caoutchouc, either by using appropriate solvents, such as bisulphide of carbon or mineral naphtha, or by the employment of hot kneading rolls, by means of which the mixture is effected mechanically. In the latter case, the temperature is elevated until the mixture acquires the desired degree of plasticity. The improved compound may be used as the base for a waterproof varnish, in which case it is preferable to effect the mixture by dissolving the cativo and caoutchouc, in any desired proportion (for example three parts of cativo to one of caoutchouc), in bisulphide of carbon, naphtha, or other solvent, to which may be added linseed oil, tar, or asphalte, or either of the ingredients ordinarily employed in the manufacture of varnishes from caoutchouc. When it is desired to produce a vulcanised product, the patentee prefers to effect the mixture of the cativo and caoutchouc mechanically by the use of the ordinary kneading rolls, by means of which he, at the same time, incorporates into the mixture the ingredients ordinarily employed in the formation of caoutchouc compounds preparatory to subjecting them to the ordinary processes of vulcanisation. By vulcanising the compound with, say, five per cent. of sulphur, he obtains a strong elastic product. For special purposes the proportion of sulphur may be largely increased, so that the product will acquire additional hardness. Metallic oxides, carbonates, or other solid substances may be mixed with the compound for increasing its weight or bulk, or for other purposes. For example, a product suitable for application to canvas may be made by using the following ingredients, in or about in the proportions named; that is to say, for example, cativo 23 parts, caoutchouc 23 parts, whiting 36 parts, white-lead 7 parts, litharge 5·5 parts, sulphur 5·5 parts. The vulcanisation of the mixture is effected by subjecting it to a temperature of about 275° Fahrenheit.

Another waterproofing compound which appears to be novel is that patented on behalf of M. Bellefroid, of Cureghem, Anderlecht, Belgium. It is described as an impermeable coating, and consists firstly of a solution of stearine pitch, one of the by-products of candle making, which pitch, in order to be used in the fabrication of the compound, must previously have been completely oxidised by exposure to the air. In order to complete this oxidisation the pitch must be spread out in very thin layers, and exposed to the outward atmosphere for a period of at least two years. This exposure is absolutely necessary, judging from experiments repeatedly made. The solution is afterwards effected in the following manner. A mixture consisting of 75 kilogrammes of stearine pitch, 15 kilogrammes of water, and 5 kilogrammes of caustic soda at about 35° to 36° is put into a boiler or vessel of any suitable shape, having a second or double bottom so as to allow of the removal of impurities which will settle at the bottom of the vessel. The mixture is boiled for 12 hours over a strong fire, after which [illegible] litres of water are added, and the boiling continued for another 12 hours. The solution thus obtained is then poured out in an open vessel, and left exposed to the open air for eight days, for the purpose of being clarified and enabling the impurities therein contained to settle at the bottom. The solution obtained according to the above process has the property of thorough impermeability.

THE "OTTO" GAS-ENGINE.

MESSRS. CROSSLEY BROS., Limited, of Manchester, have recently added an important improvement to their gas-engine. This consists of a self-starting apparatus, by means of which the engine can be put in motion by simply opening a valve.

The apparatus consists of a small receiver, into which the engine exhausts for a very short portion of its stroke the burnt gases which result from the ignition of the charge in the cylinder. These gases fill the receiver, and in the course of half a minute raise a pressure in it nearly corresponding to the pressure in the cylinder during the moment of ignition.

These stored burnt gases are admitted again to the cylinder at the moment of starting, by a very simple piece of mechanism, and thus put the engine in motion in much the same way as steam moves a steam-engine, thus saving the trouble of pulling the wheel round to get in the first charge. This little apparatus was patented three years ago by Messrs. Crossley. It may be applied to existing engines.

ON THE VALUE OF DIAPHRAGMS IN PHOTOGRAPHIC LENSES.*

MANY an amateur, on commencing landscape work, is troubled by the various stops applied to the lens he possesses not bearing any definite relation to the fixed aperture of the lens, so that even if he knows the rule to square the exposure for each decrease in size of the stop, he is still in trouble on account of the numbers on them not having any definite relation; and, further, if he tries to use another lens after having got used to his own he is rather worse off than before, for a time at least. All photographers know that different lenses possess different rapidities, but yet this difference is more apparent than real, the whole difference lying in the stops.

In order to define accurately the size of a diaphragm used in any lens, a formula is generally given for it, it being generally written as an italic "f" divided by some number; for example, $\frac{f}{1}$. This simply means, assuming that "f" means "focus," the length of the focus of the lens divided by some figure that will give the size of the stop.

---

* Approximate prices may be of service to readers who have had little to do with the tool shops, bearing in mind that they will vary slightly with different manufacturers and local dealers. A respectable ironmonger will keep only the tools of approved makers, whose names are usually a guarantee of the excellence of their wares.

* By Dr. Scott, extracted from a paper read before the Photographic Society of Ireland.

Thus, if we have a lens of eight inches focus, and find by measurement that the largest stop be half an inch, on dividing the latter into the former we get 16 as a result. Now write this as $\frac{f}{16}$, and we have the exact relation of the stop to the focal length. If another stop measures quarter inch, the resulting fraction will stand $\frac{f}{32}$. By this simple means we see at once that the latter stop is one-half the size of the former, and that it will require four times the exposure. Again, should it be necessary to have two different lenses in use, as it may not always be possible to have them of the same class—a short focus symmetrical, and a long focus single landscape lens, for example—some means of comparing the rates of exposure should be at hand. In two such lenses at present in my possession I find that the full aperture of the single lens is $\frac{f}{13}$, while that of the symmetrical lens is $\frac{f}{16}$. On squaring these, the relation stands pretty near as 1 is to 1½, so that the latter lens requires an increase of exposure in that ratio. From this we see that all lenses possess the same rapidity, *provided the stops bear the same relation to the focus*; the great difference in the rapid lenses over the slow ones being that they can work with much larger aperture.

In order to equalise the various makers' lenses, the Photographic Society of Great Britain have recommended what is termed a "uniform system" of numbering the stops. They recommend that all the stops having the formula $\frac{}{4}$ be stamped with the figure 1, this being the largest aperture that it is at present possible to make, and every other stop with that number which would indicate the exposure in comparison with the standard $\frac{f}{4}$, without regard whether all the stops can be found in the lens or not. The figures would run thus:—

$\frac{f}{4}$	$\frac{f}{5\cdot6}$	$\frac{f}{8}$	$\frac{f}{11\cdot3}$	$\frac{f}{16}$	$\frac{f}{22\cdot6}$	$\frac{f}{32}$	$\frac{f}{45}$	$\frac{f}{64}$
1	2	4	8	16	32	64	128	256

The intermediate ones by calculated proportion. If this was carried out by all makers, no matter what lens we took up, the exact rapidity could be seen at a glance.

I calculate the formula of the various stops in the lens, and select three or four of those that bear a direct proportion to each other, so that the exposure may be, say, the middle stop four times the full aperture, and the small one four times the middle, and consequently sixteen times the full aperture.

Elevated Coral Reefs of Cuba.—Mr. W. O. Crosby (*Proc.* Bost. Soc. Nat. Hist.) describes the elevated coral reefs of Cuba, and from them draws inferences adverse to those drawn by Prof. A. Agassiz from examination of the Florida reefs. Four coral terraces extend, with slight interruptions, round the entire Island of Cuba. In the western part of the island they are the predominating formation, and are well preserved on the summits of the highest hills, but, further east, erosion has been more rapid. The lowest terrace on the northern side of the island rises 30ft., the second rises abruptly 200ft. to 250ft. above it, the third is about 500ft. high, and the fourth has a height of probably not less than 800ft. near Baracoa. Five miles west of Baracoa 1,000ft. of the upper part of a mountain is reef limestone, and originally the formation must have been 2,000ft. thick. The thickness of the reefs here and upon the Island of Jamaica, where the elevated reefs reach a thickness of 2,000ft., is considered by Mr. Crosby to prove that they were formed in shallow water during a period of slow subsidence, according to the theory of Darwin. There does not appear to be any reason to doubt Mr. Crosby's conclusions in this case, neither does there appear to be any reason to doubt those of Prof. Agassiz in that of the Florida reefs. The latter authority does not endeavour to set aside the theory of Darwin; but to show that in some cases, at least, coral reefs are but the summit of an elevation formed by other agencies. In cases of subsidence the reefs are thick, while in regions of elevation, as in Florida, the coral reef is but a thin crust topping a bank of deposited matter.—*American Naturalist.*

Waterproof Luminous Paper.—For preparing a waterproof paper which will shine in the dark, the *Papier Zeitung* gives the following mixture: 40 parts paper stock, 10 parts phosphorescent powder, 10 parts water, 1 part gelatine, and 1 part bichromate of potash.

SCIENTIFIC NEWS.

THE death of Dr. Schmidt, the director of the observatory at Athens, has been announced in the newspapers in connection with the public funeral at which the King and Queen of Greece attended. Johann Friedrich Julius Schmidt was born at Eutin, Lubeck, in 1825, and after studying under Rümker at Hamburg, went successively to the observatories at Bilk, Bonn, and Olmutz. He was appointed director of the Athens Observatory in 1858, and for 25 years, with inadequate means, he contributed greatly to the progress of astronomy by his observations of comets, variable stars, and meteoroids. His famous Map of the Moon, which may be described as his *magnum opus*, was commenced in 1843, and for thirty years Schmidt added drawing to drawing, until in 1878 the map was published by the German Government, on the scale of seventy-five inches to the diameter of the moon. Dr. Schmidt was elected an associate of the R.A.S. in 1874.

We have also to announce the death of Count Th. du Moncel, the famous French electrician, which occurred suddenly at the end of last week. His works on the telegraph, the telephone, electric light, &c., are very popular in France, and one, if not more, have been translated into English. The Count du Moncel was latterly the editor of *La Lumière Electrique.*

Dr. J. Palisa, with the assistance of some very high and notable personages in Vienna, has found names for his three anonymous small planets. No. 220 he proposes to call Stephania, 221 Eos, and 222 Lucia.

Mr. C. Homersham, C.E., has been engaged for some time in boring for water at Richmond, Surrey, and although he has not yet been successful, the work accomplished is of very great interest. The boring has reached a depth of over 1,300ft., which is stated to be lower than any well in the London basin, and according to Prof. Judd, to whose care the cores have been intrusted, pebbles of coal-measure sandstone and fragments of anthracite have been found in a series of Oolitic strata lying beneath the gault. These Oolitic strata, which are found at a depth of about 1,150ft., consist mainly of limestones, but include a thin band of clay peculiarly rich in fossils of the age of the great Oolite. They are 87ft. thick, and form a new discovery in the London basin.

The Royal Society has appointed a committee to collect the various accounts of the volcanic eruptions at Krakatoa and the attendant phenomena.

Prof. Davidson, of San Francisco, has received a report of the volcanic eruption in Alaska last October. Dense masses of smoke and flame were observed to shoot up from Mount St. Augustine, vast quantities of pumice stone and dust fell, and the mount was found to have split into two, the northern portion sinking to the level of the surrounding hills, while a new island arose in the passage between Chernaboura Island and the mainland. The whole peninsula seems to have shared in the display of the subterranean energy, for not only was Ilianna fully at work, but two extinct volcanoes resumed their offices by sending up clouds of dust and stones accompanied by volumes of smoke.

A Government Bill has been introduced by Mr. Courtney for conferring further powers on the Commissioners of Public Works in Ireland, enabling them to acquire land for the purposes of the Act of 1877, which relates to the erection of a science and art museum, and the establishment of a national library in Dublin.

The Council of the Royal Meteorological Society purpose holding an exhibition of thermometers on March 19, when they will be glad to include any new meteorological apparatus invented since March last, as well as photographs and drawings of interest to meteorologists.

The Hotel Dieu, the largest hospital in Paris, is about to try Edison lamps in some of the wards.

It is stated that M. D. Monnier, with a Skrivanoff battery, weighing a trifle more than 3½oz., recently obtained during one hour an E.M.F. of 1·45 volt, and a current of 1 ampère. We described this cell on p. 82, Vol. XXXVI.

The case of Daniel Drawbaugh, as an inventor of the telephone, seems to be a very strong one. He has nearly one hundred and fifty witnesses to prove that they had seen and tried his telephones long before Bell's were heard of. It appears that Drawbaugh invented a practical instrument in 1866, and by 1874 had produced several devices, some of them as perfect as any in use at the present time.

In the course of one year, in the Municipal Laboratory of Paris, 3,361 samples of wine were examined, and more than one-half found to be bad, while 202 were positively dangerous. Of 1,037 samples of milk and cream, 542 were bad, and of 71 samples of preserves (fruit), no fewer than 25 were found to be dangerous. Of 92 samples of water, 63 were pronounced dangerous.

Preparations are being made at the Johns Hopkins University, Baltimore, for an elaborate series of tests to determine the exact value of the ohm.

Professor Hull, who has returned with his party, brings with him materials for the construction of a geological map of the Holy Land, in advance of anything hitherto attempted. He has traced the ancient margin of the Gulfs of Suez and Akabah to a height of 200ft. above their present level, so that the whole country has been submerged to that extent, and has been gradually rising. As one most interesting result of this rise, the professor is of opinion that at the time of the Exodus there was a continuous connection of the Mediterranean and the Red Sea. As regards the Dead Sea, he has discovered that it formerly stood at an elevation of 1,400ft. above its present level—that is to say, 150ft. above the level of the Mediterranean. The history of the gradual lowering of the waters will form a special feature in Professor Hull's forthcoming report.

The death is announced of Herr Hoffmeyer, the head of the Meteorological Institute of Copenhagen.

A remarkable case of "healing by faith" reported to have occurred near Dudley. A young woman, of Brockmoor, has been confined to bed for the past twenty months, suffering from paralysis of the muscles of the neck, and unable to raise her head. On Monday last she was visited by several members of the Salvation Army, who prayed with her, and it is stated that whilst they were praying the girl called out "God is healing me!" and sat up erect at once without any assistance. Both the girl and her mother believe that the change was effected by the power of prayer. The recently-exposed fraud at Whitstable indisposes one to consider these cases very seriously.

New Determination of the Ohm.—Preparations are now being made upon an elaborate scale at the Johns Hopkins University, at Baltimore, under the direction of Prof. Rowland, for the exact determination of the value of the ohm. Two principal methods will be employed. First, the resistance will be found by means of the mechanical equivalent of heat. The apparatus used by Prof. Rowland, in his well-known work on that subject, has been set up for this purpose. It is proposed to heat a non-conducting fluid, such as alcohol or turpentine, by heat developed in a conductor whose extremities are kept at a known difference of potential. The same temperature will then be reproduced under like circumstances by mechanical means. The resistance of the conductor will thus be determined directly from the work equivalent of the heat developed in the conductor. The second method to be used is that of Kirchoff, as modified by Rowland in his determination of the ohm in 1876: most of the instruments will, however, be new. If time permits, the earth-conductor method of Weber will also be used. Fifty Planté cells charged by a small dynamo machine will supply the electricity in the calorimetric method. For measuring large currents, an electro-dynamometer has been constructed with the Helmholtz arrangement of two large coils and a single small suspended coil.

M. REYNIER has suggested a modification of his maximum cell to serve as a standard of electromotive force—namely, a cell having a large copper electrode, and a very small amalgamated zinc electrode, immersed in a solution of sea salt. According to M. Reynier, this battery has an electromotive force 0·82 volts, and maintains this value within 1 per cent. even when the circuit was passed for two hours through a resistance of 820 ohms. M. Reynier prefers this combination to one containing sulphate of zinc in solution, because of the liability of the latter salt to contain free acid.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor of the English Mechanic, 81, Tavistock-street, Covent-garden, W.C.

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

*** In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks: a vice from whence great inconveniences derive their original."—Montaigne's Essays.

[illegible]—PICARD—PLATO.

[illegible]—Mr. [illegible] sketch on p. [illegible] evidently shows that the [illegible] which I saw east of [illegible] p. [illegible] is that which he calls [illegible], and not as I supposed [illegible]. I am surprised that I did not see [illegible] as he has found [illegible].

Mr. [illegible] asks, p. [illegible], which of the ridges mentioned in the [illegible] for Feb. [illegible] I meant when I said that the ridge [illegible] between Picard and Peirce, in his [illegible] on p. [illegible] might be the same as the one mentioned there.

It was the ridge mentioned as being between Picard and Peirce that I referred to. Though the two descriptions are not exactly the same, there seemed likely to be a connection between the observations—that perhaps it was the same ridge seen under different illuminations.

Since my former reply to Mr. Gemmill I had a [illegible] view on Nov. [illegible] of the valley [illegible] Plato which I there mentioned (p. [illegible]), [illegible] to be perhaps its southern extremity. It is a broad and shallow valley, tapering to its southern end, and extending northwards for a long distance. It is bounded on either side by ranges of hills. I should like to have sent my drawing of it, but the view was so unusually fine, and my efforts to represent it so feeble, that I fear it would not "pay" for the trouble of printing.

Mr. Gemmill must excuse me from entering into further discussion respecting the study of selenography. As it appears to be simply a question of words or opinions between himself and me, there does not seem anything to be gained by doing so, and it is not easy to make time to do more than note a few notes of things observed. M. A.

ASCERTAINING THE MOON'S AGE ON ANY DAY OF THE MONTH.

[illegible]—In your issue of Feb. [illegible], of 188[illegible], I observe that Mr. James Pearce, &c., submits, among other curious problems, one for "ascertaining the moon's age on any day of the month, in any year in the past, present, or future, &c."

I am sorry to have to question any statement from so eminent an "authority," but the rule given does not work. I have made the experiment for every month in the century, and not in a single instance is the result as it should be. The No. [illegible] which is to be added—is not this the Epact? And if so, should it not vary for every month, and is no notice to be taken for leap years?

Take the present day, Jan. [illegible], 1884.

[illegible]

[illegible] = [illegible] = [illegible]
[illegible] century = [illegible]
= [illegible]
Months March to January .... [illegible]
Day of month .... [illegible]
Add No. [illegible] .... [illegible]
[illegible]
The century .... [illegible]
[illegible]

[illegible] days old, whereas it is but three days old.

Major Trasseweather.

[illegible] Observatory, Tierra del Fuego, [illegible], Jan. [illegible], 1884.

COMET PONS-BROOKS.

[illegible]—I [illegible] sketch of comet Pons-Brooks as drawn by Mr. [illegible] on the evening of Jan. [illegible], 1884, with [illegible] refractor, power [illegible].

The [illegible] letter of Mr. Edwin Holmes ([illegible], page [illegible]), might perhaps well be ignored. Yet, for his satisfaction, I will state that the highest power eyepiece used in connection with our [illegible] refractor, as given by the maker, magnifies [illegible] diameters, and when used with the Barlow lens, which I was informed doubled the power of every eyepiece, produces a magnifying power of 1,024 as stated. A simple case of multiplying by two—an arithmetical feat which, I presume, Mr. Holmes is doubtless capable of performing.

N
E
SCALE
MINUTES OF ARC
PONS BROOKS, COMET. 1884. JANUARY 21st 13h G.M.T.

With reference to Mr. Holmes's latter criticism, I simply reiterate that there are no features (barring those heretofore named) in Trouvelot's drawing of the planet Saturn which cannot be seen, and *well seen*, in our 6¼in. refractor under favourable atmospheric conditions, such as existed upon the night in question.

It is scarcely necessary for Mr. Holmes to quote Dr. Kitchener, or any other authority, to convince anyone having had twenty-four hours' experience with a telescope, of the uselessness of employing such enormous magnifiers except for purposes of experiment.

This power was employed solely for such purpose of experiment, and the result communicated to you, Sir, with other intent than that of a hoax.

W. C. Gurley.

Marietta Observatory, Jan. 26th.

STAR COLOURS AND NAKED-EYE OBSERVATIONS.

[illegible].]—I had expected to see something from the pen of our good friend, the Rev. T. W. Webb, in response to the appeal by Mr. Gemmill (letter [illegible], p. 495); but, pending this, I will endeavour to give the result of my own limited experience. With respect to the employment of an opera-glass for the observation of star colours, I fear its range is too limited to be of much service. For moderately bright stars, I should recommend a refractor of about 4in. aperture, in which the over-correction of the o.g. should be very slightly seen; and, in my opinion, Wray's o.g.'s most nearly fulfil this condition. The faintest stars are more suited to a reflector, which might be 6in. or upwards in aperture.

As to magnifying power, a *good* Huyghenian eyepiece of [illegible] to 120 diameters is as useful as any, although some of the achromatic eyepieces are very fine for this class of work. Very often, in the case of double stars, a slight displacement of the image from the focal point will assist in the estimation of the separate colours. A bar in the field of view may also be employed to hide one of the components whilst viewing the other. In all cases, the star under examination should be kept near the centre of the field, as the edges are not usually achromatic. The proper description of star colours is a difficult task, from want of comparison with a definite standard. A small spectroscope, with a Swan incandescent lamp as a source of light, might be readily attached to the telescope, near eyepiece, for purposes of comparison; but, again, there are scores of star tints not to be found in the spectrum at all. I freely acknowledge that my own attempts at describing star colours are very unsatisfactory to myself; and I should feel extremely thankful could I see a really trustworthy and workable method, whereby these results might be secured without that personal equation which is so detrimental; but at present I do not. One serious source of error lies in the artificial light used to register the observations by. Gas and oils are more or less yellow; petroleum is whiter, but its odour unpleasant, and apt to give one a headache. The electric incandescent lamp is probably the best, and certainly the most convenient, form of light for the amateur's use. Whatever be the light, when going from it to the telescope, a brief rest should be given to the eye before applying it to the eyepiece.

Variable stars are, perhaps, the most useful objects to examine with the naked eye or opera-glass, and Mr. Gemmill himself is quite competent to advise on these.

Hastings, Feb. 15. **W. S. Franks.**

THE EFFECT OF MIST AND HALOS ON DEFINITION—JUPITER.

[22361.]—I may supplement my remark, that "F.R.A.S." confirms, that mist of a certain kind improves the definition of Jupiter, by the following fact which I have also noticed, and particularly so on December 12, 1883, and January 8 of this year. On both nights there was a mist and prismatic halo round the moon, and on January 8, while the mist was passing over the moon, the halo being present, every detail on her surface stood out sharply and with the greatest distinctness; but the next minute mist of a different kind passed across, and though it did not appear to the eye to be at all thicker than the first mist, yet it completely blotted out all detail. The effect was curious, as the swiftly passing mist thus changed from one kind to the other every minute or two, though with no perceptible difference in appearance; and one moment definition was perfect, while the next nothing but the largest features could be seen, and those considerably dulled. On December 12 a star shone brightly through the violet part of the halo, and dimmed through the orange, as the halo waved from side to side. The whole sky was covered with thick misty clouds, and when a mist followed the halo across the moon and star, though it appeared no thicker than the mist of the halo, yet the star could not be seen through it. Thus we see that two mists, with no perceptible difference to the eye, may differ considerably in thickness or in absorbing power. While mentioning haloes, I will remark that I have seen it stated that prismatic haloes are very rare. This I do not think is so. I have made a habit for some years past of putting down all the haloes I have seen of every kind, and prismatic ones I very often see through the nights. I have noticed, however, that they are very rare before 11 or 12 p.m. Some of the rapidly shifting ones are of great beauty. I have sometimes thought of sending my catalogue of haloes to the English Mechanic, but I suppose it would not be of any use. If, however, any one thinks it would be, I will send it; it dates from 1877 until now, with a few in 1860 and 1861.

Did any one observe on February 11, at 14h., that the southern half of Jupiter, from the south equatorial belt to the pole, was of a greenish-yellow colour? It was very conspicuous to me; but was, I suppose, due to some atmospheric cause.

M. A.

MEASURING POWER OF TELESCOP

[22362.]—Every method yet devised for the purpose seems to be open to some objection. The plan of setting up marks at 100 yards or so fails for the simple reason that the power on an object at 100 yards is very different to the power on a star, while dynameters differ in results, and with a high power it is difficult to judge exactly when the small circle of light just touches the sides of the tapering slot. My object, however, is not to point out faults, but to suggest a method which requires no special apparatus and no special training, and yet is reliable, accurate, and easy.

Take the eyepiece whose power is desired in front of a window, and look through it. A circle of light will be visible, which is the field of view. Step back or forward until this circle of light just exactly apparently equal to the clear opening of the window. Measure the distance from centre of window to stop of eyepiece, and measure the clear opening of window. Draw a line on paper as many inches in length as window is feet in width, and set up a perpendicular from centre in same proportion to distance from window. Join the ends of first line and perpendicular, and measure the angle at vertex. This can be obtained by calculation as easily, and is the angular field of view. Now put the eyepiece in the telescope, and time the passage of an equatorial star across the field. Turn this into seconds of arc, giving thus the angular diameter of actual field. Divide the first obtained angular field of eyepiece by this actual field in sky, and the power of the eyepiece on the o.g. or mirror in use is obtained in a moment. This is much simpler in practice than it looks on paper. Instance, I find field of eyepiece in my possession 25° apparently. An equatorial star passes through field in 25 seconds. This is 375″ of arc; 25° = 126,000″, and this divided by 375 gives 336 for the power. **E. Holmes.**

GLACIERS AND THEIR MOVEMENT.—II.

[22363.]—In the English Mechanic for Dec. 28th of last year (letter 22185), I gave a rough outline of some of the many theories which have been adduced by eminent travellers and observers on the subject of the "movement of glaciers." To those I would now add but one more, thus to show how hard a problem it is, and how much more there yet is to be observed before we can feel at all sure that any explanation offered is the true one, and to the full really gives a complete and final explanation of the phenomena. To the eminent authorities already cited, I would now add that of M. Rendu, Bishop of Annécy. The Bishop is here a great authority, and he has, by force of original researches, which makes all he says on this subject well worthy of study, thrown much light on it. Professor Tyndall says of him that he was of those who had an extraordinary faculty of observation, and an intuitive power concerning things yet untouched by experiment, belonging but to the few. This observer compares the glacier to a river, and says there is a resemblance so complete between rivers and glaciers that it is impossible to find in a river any circumstance which does not exist in a glacier—*e.g.*, between the Mer de Glace and the river nearest to it, the resemblance is complete. By this theory it is therefore evident that should the snow which feeds the glacier from any cause cease to fall, the glacier would in time nevertheless, empty itself from its bed, and leave it dry—as flowing water would do. But will those who have observed and thought about that difficult problem admit this as a sufficient explanation of glacier movement? M. Rendu calculated, it may be here added, that about *five feet* of ice is added each year to an Alpine glacier, and that this would make Mont Blanc 400ft. higher in each century, and 4,000ft. higher in a thousand years.

But the sole hint that the Bishop has thrown out as to the *cause* of the glacier movement is this: he says that, notwithstanding the hardness of the ice, it can but support a given pressure, without either breaking or being squeezed out; and thus it is, as he puts it, that the movement of the whole mass, or masses, of matter forming the glacier, follow of necessity. These theories are, it must be allowed, not a little ingenious; but they would certainly seem to be insufficient to fully account for glacier movement. And it is this which has led me to venture on yet one more attempt at an explanation of the puzzle of it; and I have been led to this partly by the study of one or two very simple experiments, and partly by the accidental observation of a curious fact in a not-distant snowstorm. These experiments and observations may be perhaps familiar to some; but they will bear repetition, and will at least be of interest to the traveller and glacier student. All know, or may by observation know, the look of, and how the sand falls and heaps itself up in a common hourglass. The sand does not level itself as it falls as a liquid would do, but assumes a conical form, the sides of which take an angle of about 35°. The same, of course, follows if fine sand be made to fall from a funnel on to a flat horizontal table. Any height of cone may thus be reached. Now, if this horizontal table be raised at one end, and made to form, in miniature, a mountain slope, say, to an angle of 30° or 40°, and then towards the upper end of it a cone of sand be gradually formed as above, it will be found that the dip of the incline does not alter the conditions of the experiment further than to make the lower slope of the cone of sand the longest and the upper one the shortest. However much the cone of sand may be added to, there is no tendency in it, as a mass, to slide down the incline until the incline, being made by degrees steeper and steeper, the cone of sand at last, all of it together, tumbles down the slope in a confused heap by sheer force of gravity, like a snow avalanche or a heap of rock débris down a mountain side. In no case, certainly, does sand or débris, or fine dry snow, as it falls and exists on the top of a snowclad mountain, come down into the valley as a glacier does. It falls, but as an avalanche falls, not as a river flows.

But now take what is termed a "viscous" substance—a semi-fluid, such as tar, or what is better for experiments on a small scale, common thick treacle, and what is the result if we repeat the above sand-heap experiments? The whole process and result is different. This "viscous" or semi-fluid matter cannot be piled up into a conical heap as sand or gravel; each additional quantity, as it comes from the source of supply, sinks into the mass as it spreads out in a circular form on the level table. Each additional quantity, instead of piling itself up in a conical form as the sand does, sinks into the mass beneath, and in doing so forces out the matter round it and on which it falls, and thus enlarges the circle of it. Now, if this same experiment be repeated on an inclined plane, as in the above experiment with the sand, the result will be found most curious and instructive, and will, perchance, guide to an apprehension of the primary cause of glacier motion. This "viscous" mass, as it accumulates, does not on this sloping surface, as on the level one, spread itself out into a circular form, but begins, as might be expected, to run slowly down the inclined plane in a long and elliptical form by mere force of gravity, and more or less rapidly according to the steepness of the incline. Suppose the angle of this incline or valley to be, say, 30°, observe the rate at which the viscous matter flows, the supply continuing regularly from the funnel at the top of the incline. Now lower the inclined plane to an angle of 10°, the same supply still continuing, and the result will be a diminished rate of speed, and a more sluggish flow of the viscous matter, whatever that may be, but without other change. This experiment may be usefully varied by trying different angles of slope.

But now again change the conditions of the experiment, and stop the supply of fresh matter from the funnel at the top of the incline, and the result is a little surprising: the flow of this model glacier almost wholly ceases; indeed, if the surface of the incline be at all rough, it stops altogether, the weight or gravity of the mass not being—by itself and alone—sufficient to urge it down the slight incline. Thus, as it has been contended so strenuously, the force of gravity alone is not sufficient to urge the mass of a glacier down a slightly inclined valley, whatever it may do down a steep incline. But all else remaining as before, again allow the supply of viscous matter to pour down on the head or source of this miniature glacier, and the flow, however slow it may be, immediately recommences down the whole length of the stream, and this it does, not only by the fact of the fresh supply flowing down upon it, but by the *pressure* or the *impetus* the fall of it thus acting on the whole mass gives it, and thus forcing it slowly downwards. This is a most instructive and suggestive experiment, and needing repetition on a large scale, and with different substances. It would seem to point to the *origin* of glacier motion, and to indicate how it really is that a glacier moves, and how far gravity or the weight of the glacier mass acts in drawing it down the incline of the mountain slope, however slight that may be. This experiment may be varied in a great variety of ways; but, however varied, the results are invariably the same, all tending to prove that the force which moves the ice glacier downwards and forwards is the constant pressure of the—ever being added to—great ice and snow "reservoir," as M. Rendu terms it, at the mountain top, and the *striking* force of the snowfalls. It is to be observed, and it must be borne well in mind, that a glacier, whatever the cause may be, flows as a viscous stream of matter—flowing, spreading, narrowing, and then widening, and again narrowing and bending, just as a viscous substance—*e.g.*, tar—is found to do, or as melted lava does down a volcano slope. In the illustration as above cited, we have supposed that the ever-renewed supply from the head of the glacier comes from a single point of supply, as from the mouth of a funnel; but precisely the same result comes from a like supply if split up into a number of small streams, as from the mouth of a watering-pot, with a number of separated small holes together acting like a wide-spread shower of viscous rain or snow. So striking is this experiment, especially if performed with different thicknesses of "viscous" substance, and with different inclines, representative of different slopes of the mountain masses, that it is all but impossible to do otherwise than to admit the enormous power exerted, not alone by the pressure, but by the *striking* force of the snowfalls and the ever-accumulating masses of matter—*i.e.*, of snow and ice at the glacier head at the "reservoir" glacier. Indeed, to go to the mountain top itself to the head of the glacier as to that of the Glacier des Bois, where is to be found a marvellous "sea of ice," as it has been described, and where the surface is horizontal, or nearly so. Here there is a constant advance of some 40ft. per year of the snow from, as I interpret it, the simple pressure of the constant *snow-fall* above it—a singular illustration on a gigantic scale of how these wonderful forces in nature act, and how simple at times is the cause of so much that is obscure.

I would add yet another illustration, and it is instructive, as coming from a quarter of the world out of the ordinary routes. On reaching the middle of the La, or Pass, on the way to the glacial lake, at the summit of it, says Mr. Wilson, it becomes at once apparent where its sea of ice comes from. On every side is to be seen the steep slopes of snow, or "nivé," with immense beds of snow overhanging them. A dazzling sheet of unbroken snow rises up for more than a thousand feet at a steep incline to vast over-hanging walls of what may be termed "stratified nivé," and from which huge masses, or fragments, every now and then come down with loud and thundering noises like the shattering into fragments of the very mountain itself. A huge cataract of snow and ice is forced down and over the edge of the incline, or table, on which it accumulates by the continual pressure of the snow above. This "glacier flow" is to be seen on the higher peaks of the Himalayas, where the glaciers are of enormous thickness and width, and by the side of which the Alpine glaciers and heights are but small, indeed, in comparison, huge and impressive as they are. Mr. Andrew Wilson, who traversed this "abode of snow," it is useful to observe, would seem to have come to the conclusion that the "heat of the sun" is the power which moves the glacier mass, and causes it to "creep down" the mountain hollows and valleys. If this be so, how, it may be asked, does the heat *act* so as to become a propelling or a dragging power? For that is, indeed, the problem.

I have thus ventured to indicate, or rather to hint at, the primary cause of "glacier motion," in the hope that many who visit year after year Alpine regions, where the phenomena may always be observed, will follow up the curious inquiry. It is at all times found advantageous to look at such phenomena with a theory of some sort—a plausible one, and one which at least seems to account for them—rather than to see and have none at all. I think that by dint of patience in looking at, and by attentively studying, the upper glaciers, their mode of movement might, in a degree, soon become visible. But, be this how it may, there can be but little doubt that many a crude and haphazard conjecture has proved eventually to herald in the advance of a great scientific truth—in this instance of the *cause* of glacier motion. Even an insufficient cause, or one acting only partially, may yet lead to a complete and comprehensive solution of the problem. It may indeed be true that not a single snowflake or a single drop of rain falls on to the summit of a snowclad mountain, or on to the slowly creeping glacier, which does not, in the very act of falling and striking it, as well as by its gravitating force, help to move downwards the vast, and as it looks, immovable mass and masses of ice and snow.

C. B. A.

THE INTERNATIONAL INSTITUTE FOR PRESERVING AND PERFECTING WEIGHTS AND MEASURES.

[22364.]—I fear that the hope expressed by your correspondent, "F.R.A.S.," in letter 23331, that under the auspices of the above Institute, accurate measures of the Great Pyramid will be made "by men who have no theory to support," is somewhat too sanguine. In the library of the Royal Astronomical Society is a copy of Vol. I., No. 4, of "The International Standard: a Magazine devoted to the Preservation and Perfection of the Anglo-Saxon Weights and Measures, and the Discussion and Dissemination of the Wisdom contained in the Great Pyramid of Jeezeh. Published by the International Institute for Preserving and Perfecting Weights and Measures." Judging from its contents, one would scarcely suppose the Institute to have "no theory to support."

The number contains, among other articles, a paper, proving to its author's entire satisfaction that certain chambers in the Pyramid give a clue to the Solar system of the ancients, the dimensions of the chambers representing the extent in the heavens of certain zodiacal constellations; a paper on the "Buried Cubit," showing that the British yard is everywhere present in the pyramid measurements, thus giving "a special identification of the British with the Lost House of Israel"; and a wild rhapsody on "Zechariah's visions of the Pyramid cap-stone, and of the wicked measures." The magazine closes with an "Inquirers' Club," in which is the horoscope of the late President Garfield, noteworthy for the fact that the President apparently did not live *quite* long enough to satisfy theory; but that "it will always be a matter of conjecture among students of astrology whether or not he would have reached this point if decisive steps had been taken immediately after the shooting, and a removal made to a locality designated by Jupiter in Aquarius." So the predictions of the stars may be falsified by the mistakes of our physicians—an important admission!

"F.R.A.S." is right on one point: the Institute is an uncompromising foe to the metric system: here the "Standard" gives no uncertain sound. I subjoin one verse from a charming poetical effusion which adorns its pages, "A pint's a pound the world around":—

"Then down with every 'metric' scheme
Taught by the foreign school,
We'll worship still our *Fathers'* God!
And keep our Fathers' '*rule*'!
A perfect inch, a perfect pint,
The Anglo's honest pound,
Shall hold their place upon the earth,
Till time's last trump shall sound!"

W. H. W.

A HAND-WARMER FOR PIANISTS.

[22365.]—I must apologise for not replying earlier to letter 22309 of Mr. W. Henley Richmond in the "E. M." of 1st inst. My hand-warmer is fixed to the piano by means of two small pieces of bent band-iron screwed under the keyboard, just above the knees. Two irons projecting from the warmer slide into these pieces, and the apparatus can thus be adjusted or removed *instantly*, and cannot be displaced by any knock given it while playing. When the warmer is not required it can be removed, and as the two pieces of band-iron are quite out of sight no trace whatever of the fixing can be seen.

It would be a very long and difficult task for me to give full instructions for making my hand-warmer, and would answer no purpose, as it would be much more advantageous and cheaper for any person wishing to have one to get it made by the maker of my own, whose name I will be happy to send to anyone advertising address in the "E. M." for the purpose. **W. Ritchie.**

PUMPING BY SUCTION.

[22366.]—"Essar," on p. 499, wishes "D. L." to explain whether the water will flow up the pump barrel when the pump fittings fail to suck either air or water.

What "D. L." meant, perhaps, was this. In the act of withdrawing the air or water from the barrel, it leaves an empty space. Now an empty space is a vacuum, and can exert no power to resist the pressure of the atmosphere, so that air would rush up to destroy the vacuum: as the suction pipe is in water, the latter has to go, but under pressure of the atmosphere.

If water were to go up into a pump barrel without it having been first emptied, would not water be able to rise from the sea?

I should like "D. L." to say what is suction, if it is not the weight of the atmosphere acting on the surface of the water, and forcing it into a vacuum being created in a pipe or pump.

J. P.

[22367.]—What is the meaning of all the scientific (?) indignation evinced by "Egstow" and others in connection with the word "suction" as applied to a pump? I suppose it will be allowed that one is correct in saying a baby *sucks*; if so, in what way does that action differ from that of a common pump? The child takes the nipple in its mouth, creates a partial vacuum, and the pressure of the atmosphere on the surface of the breast causes the milk to rise into the small ducts in the nipple, and overflow into the child's mouth. Substitute vacuum produced by pump bucket for mouth, pipe for nipple, and water surface for surface of breast, and where is the difference? But "Egstow" speaks of "that feat" of suction. What in the name of common sense does he suppose suction consists in? **W. A. G.**

[22368.]—I note a paragraph under the above heading on p. 453 of your issue of January 25th last.

Assuming it to be a fact that the arrangement therein referred to does enable the suction pump to raise the water 37ft., the explanation of the case is not difficult.

The inventor of the arrangement is not the first who has discovered it, or attempted to deceive the public by its means.

In 1766, at Seville, a tinman undertook to pump from a well 60ft. deep, by a common pump, making the sucker play within 50ft. of the water. As he failed to pump the water, in despair at his want of success, he dashed his hammer against the pipe, by this act he made a small opening about 10ft. above the water, and to his great pleasure the water instantly ascended and was discharged at the spout. A surgeon of Rouen repeated the experiment with his pump; he bored a small hole in the suction pipe 10ft. above the water, to which he attached a cock; when it was open the water could be raised 35ft., instead of 30ft. when it was shut.

One Langden, about the year 1797, invented an "hydraulic machine" by which water was raised 42ft. through leaky tin pipes. Of course, the invention could raise water no higher than in the common pump, unless there was a perforation in suction pipe.

The explanation of these cases is simple, and fully confirms the theory of atmospheric pressure. The air in entering the suction pipes at the small hole became mixed with the water, which, therefore, was raised in disjointed portions or in the form of thick rain, instead of being carried up in a solid column. This mixture being much lighter than water alone, the atmospheric pressure could support a longer column of it.

If the admission of air is properly arranged, there is no difficulty in raising the compound fluid from one to two hundred feet by a common pump.

There is, therefore, not the slightest doubt but that the air pump referred to is raising a compound fluid of air and water, and the only question remaining to be answered is (and which can be only ascertained by careful examination), How the air is admitted into the suction pipe? **W. W. W.**

Newcastle-on-Tyne, Feb. 18th.

[22369.]—On the contrary, Mr. "Egstow" (p. 521), you have found the "other side" by the discovery that Ganot "used the term technically." In the "84th year of the 19th-century," it is absurd to talk about the "miscalled suction-pump," when the term is definite, distinct, and well understood—at least as well understood as sunset and sunrise. Nuttall, in his dictionary, which does not pretend to be scientific, says (I quote from memory), "Suction pump: the common pump, in which the water is raised by atmospheric pressure." It is simply a libel on pumpmakers to say they do not know that simple fact. But that is only a detail. I should like to hear what Mr. Davies or anybody else has to say about the arrangement described on p. 453. Perhaps "Egstow" will help to explain how the water is lifted 37ft., and not quibble about the application of such terms as "suck" and "suction." **Essar.**

INGROWING TOENAIL.

[22370.]—"U. C. S." (22329) puts forth a very plausible idea: but has he every tried it? Having suffered from this complaint myself, and getting no cure from the scraping, I write to say so. I also tried cutting a V-shaped piece out of the centre of the nail at someone's suggestion, but it did no good. I put a plug of cotton-wool under the offending corner to keep it out of the flesh, still it grew. I had the nail cut out and again it grew. Lastly, I took to wearing shoes with broad toes, which allowed them (the toes) freedom and no pressure, and have now been free from it a long time. If my large toes feel ever uncomfortable, I cut the nails, and am eased at once. This ingrowing nail is due, I believe, to our narrow-pointed shoes, which compress the toes together too much.

T. R. Allison, L.R.C.P., etc.

BEE-KEEPING.

[22371.]—Will some one that has had experience of the following, please advise me? Among other bee-keeping appliances at Cork Exhibition, I saw a feeder which I thought a good one. It is a round tin, about 4in. diam. and 2in. deep, with an inch hole and tube, standing 1½in. high in centre of tin. A thin piece of wood is cut to fit inside of tin, with a hole to allow tube to pass freely through. The syrup is poured in through a small lip, soldered to the outside of tin, the wood of course floating on syrup, the bees having access to same through centre tube and a number of small holes being burnt in the float, and a piece of glass laid on the top of the tin to prevent their escape.

Now, it seems to me a first-rate plan for feeding up for the winter: but am not so sure about its being adapted for stimulative feeding. Will it do to give only a very small quantity regularly in the tin, as I do not like the bottle plan of feeding? I most fully endorse every word of letter (22323) by "G. J. H." **J. Perry.**

[22372.]—I am very sorry that Mr. Abbott should have misunderstood my allusion to his leaflets. I am perfectly aware that the valuable information given in them is based on long and varied experience; they have taught me an immensity; no one can value them more than I do, and they ought to be read and closely studied by every bee-keeper. I mentioned them merely that I should not get answered by some one who, knowing nothing practically of the subject, but having got hold of some of "Abbott's Leaflets," would go quoting a lot out of them, which he most likely did not understand, and which I knew already and could read in the original, and thus an answer which was taken from a practical source would become theoretical as far as the person giving it was concerned. I have a horror of persons who seem to make it their business to answer questions on all sorts of subjects in this kind of way: though the leaflets are "exhaustive," they are so "in a general sense," and a beginner will often want a little *particular* information which may often very usefully come from one who was not himself a beginner not a very long time ago as Mr. Abbott. I have now to thank "J. I. S." for the information which he has given me as to "Examination of stocks," "Stimulative feeding," and "Transferring stocks," which is just what I wanted, and which I have got in time to be of use. As to the first two, this is the first spring that I have had bees in bar-frame hives. I therefore have no *practical knowledge* of how to manage them, and I know no one who has. We transferred stocks most successfully in July and September last, but did not know how early it could be done with advantage, which, thanks to "J. I. S.," I know now. We have made some excellent hives, the same as "J. I. S's." for all practical purposes, taking the same frame. I [illegible] made one, the first, less than 20in., and am now making a batch 21in., which I expect will be in some respects more convenient than 20in., for working with section frames at back.

I think there must be some great mistake in the scantling of timber given in "J. I. S's." hive; is it not more like that for frames than for hives? My inner box is made of ¾ and outer of inch stuff, and I have it double all round and packed with cork dust. I also have movable and [illegible] double bottoms kept well home by a wedge.

As to position, I am in a very early place, perhaps, with the exception of a few very favoured spots in counties Cork and Kerry, as early as any in the South of Ireland. I should also say it is a good place for bees, particularly so early in the season. The furze is in blossom already, and the catkins of the hazel will be in a very short time covered with pollen; there are also a quantity of [illegible] trees which flower very early, and fruit trees and quantities of both sloe, thorns, and hawthorn which flower very profusely, and earlier than either lots of Darwinii, which is now just coming into bloom. Numbers of my bees are out every fine day, though I have the doors of the hives nearly closed and a piece of board laid up against them on the flight board so as not to let any light get into the hives.

We introduced a Ligurian queen on the 1st October, and in that stock the bees are mostly Ligurians now. The bees continued breeding and working very late last autumn, bringing in quantities of both honey and pollen from the ivy, of which there is an immense quantity, up to 1st November and even after. I hope "J. I. S." will keep me in mind, and further on, give me, and others, the benefit of his experience as occasion arises, or rather *before* it is likely to arise. Has he ever tried his hand at raising queens? I hope to try as soon as it can be done, though *how soon* I don't exactly know. I have got the Rev. G. Raynor's admirable pamphlet; but would be glad to get some particular advice from "J. I. S.," or some one else, if he has not tried it, and particularly how soon it would be well to commence, which I think I would do by exchanging the combs, without any bees, of the Ligurian stock with those of a black stock, taking away the black queen and leaving the black bees to raise young queens from the Ligurian eggs in the brood comb given to them in exchange for their own. This is the plan recommended by Mr. Raynor as the safest, there being no risk of losing the original imported queen.

G. J. H.

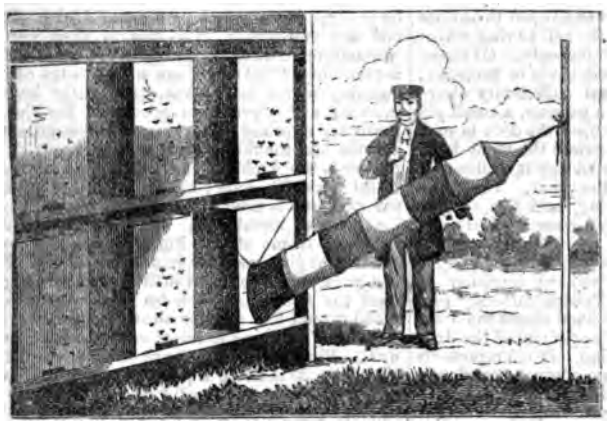
BEE FARMING IN NEW SOUTH WALES.

[22373.]—The operations in bee culture going on in Parramatta, as described in the *Town and Country Journal*, are well deserving of being ranked as bee farming, and may interest some of your readers who are reviving the interest in the subject formerly manifested in our columns, and, as will be seen, the operations are carried on after the most approved system of the German apiarians, which differs only in the form of hive used and a few minor details from the approved system followed in Britain and America. In December, 1881, a skilled bee master, Wilhelm Abram, arrived in Sydney from Germany, where bee culture is a recognised industry. He brought with him certificates of qualifications from no less authority than that of the celebrated Dathe. On his arrival in Sydney Mr. Abram placed himself in communication with Mr. S. MacDonnell of that city, an enthusiastic amateur bee keeper. Mr. MacDonnell saw the opportunity which the advent of Mr. Abram gave to establish a bee farm on a commercial scale and conducted by a skilled apiarian, and conceived the novel idea of working it as a joint stock venture. Four well-known gentlemen in Sydney joined him and Mr. Abram in the venture. As it was intended that the operations of the company should eventually be [illegible] Italian bees, a race superior in many important respects to the ordinary black bee, the concern was named the Italian Bee Company.

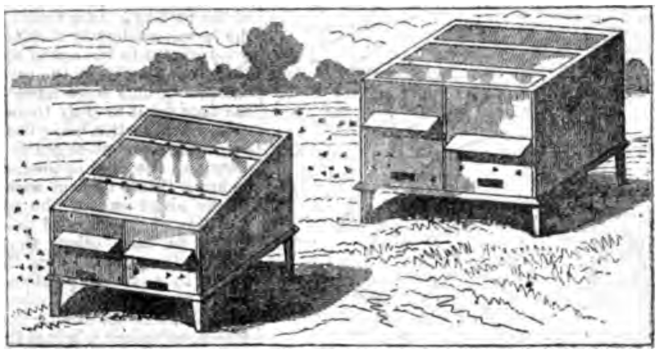
Mr. Abram, before leaving Germany, had purchased some of the prize swarms at an exhibition of Italian bees in Germany, and the Italian Bee Company commenced operations with these on a rented piece of ground at Parramatta in January, 1882. An importation of prize queens from

America was made, and the operation of queen rearing was entered on. In the mean time a number of colonies of the common black or English bee afterwards had been secured and transferred to frame hives, and as Italian queens were reared the black queens were removed and replaced by Italians, the progeny of which replaced the black bees as the latter died out. Much attention was not paid to producing honey until the race of Italian bees should have been firmly established, and the result was that in the spring of last year there were about 80 colonies of gold-banded Italians actively at work. The company before this secured the fee simple of a piece of ground in Kissing Point-street, Parramatta, where operations are now conducted. There, a few weeks since, on visiting the establishment, we saw the hives opened, the frames containing beautiful sheets of comb removed (the gentle Italian bee showing no signs of anger during the operation): the comb was then placed in a centrifugal machine, which threw the honey out by centrifugal force, leaving the comb undamaged and ready to be returned to the hives for the bees to fill over and over again with nectar.

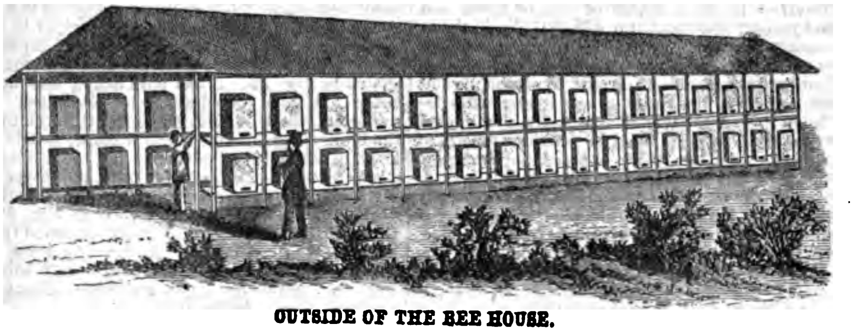
The bee master is an adept at his profession. Pipe in mouth, he opens hive after hive, blowing a whiff of smoke upon them, to give the bees something else to think about when they seem any way refractory, a projection from the stem of the pipe allowing this to be done conveniently. The hives used are of the German bar-frame kind. They open from the back, and each hive is two stories high, so that ample space can be given to the bees when they are storing honey rapidly. The main house is 150ft. in length, 10ft. high, 10ft. wide, and two tiers are arranged on each side as in sketch.



SWARMING BAG, A GREAT IMPROVEMENT.



QUEEN BREEDING HIVES.



OUTSIDE OF THE BEE HOUSE.

THE QUEEN CAGE

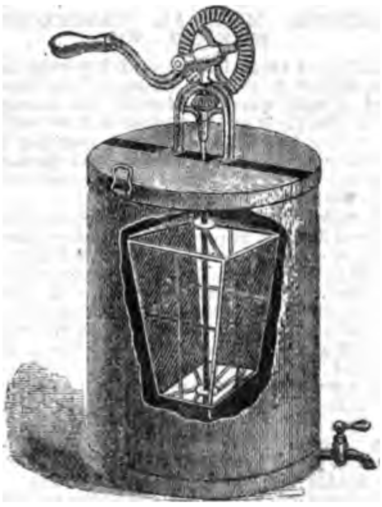
The swarming bag is one of the best things we have seen in bee culture. It is about 6ft. in length and 1ft. in diameter, and formed of alternate lengths of calico and mosquito netting, each length having a ring of cane inside, to hold out the bag as shown in the sketch. When the bees are about to swarm, the bag is fastened on to the front of the hive and the other end fastened to a stake. When the queen emerges she bounds up into the upper end of the bag, and is quickly surrounded by her followers. Thus the swarm is captured with ease, the alternate breadths of mosquito netting and calico making the interior light and enticing for the bees to enter and cluster. They are then shaken into a bar-frame hive.

The queen breeding hives are much smaller than the others, and are arranged at distances of about 20ft. apart alongside the fences. Two or three frames of brood comb are put into each hive, with a queen cell coming to maturity. When the queen bee hatches out of the cell, she makes a flight (the only flight of her life) in order to meet a drone or male bee. She is then fertilised, and becomes the mother and queen of a family, laying eggs at the rate of 2,000 daily when the season is good and stores abundant.

The centrifugal machine is used for extracting honey without destroying the comb. The caps with which the bees seal up each cell of honey are sliced off with a very thin bladed knife of simple form, and the frames are set in the metal baskets of the inside of the machine. Then, by turning the handle, the honey is thrown out and runs down the sides of the machine, from which it is drawn by a tap. In this way absolutely pure honey is got without any other substance whatever, and without injuring the bees or annoying them. The queen cage is drawn to scale, as is the queen or mother bee seen inside. In America and other places, these queen cages and mother bees are sent by post, and thus hives are strengthened and the breed of bees improved. One of the objects of the bee farm at Parramatta is to send out queens and improve the race of bees, as well as the hives and the quality of the honey. There is abundant room for improvements of the kind. From this country the very finest honey ought to be exported in quantity, although at present very poor stuff is sent us from places where glucose mixtures are worked up for honey. The bees at Parramatta are doing excellently well this season, as are also Italians recently received from Queensland. **F. N. T.**

PASSAGE OF ELECTRICITY.

[22374.]—One evening, about a year ago, I put a plate of zinc and copper in a glass cell in the usual sulphuric acid solution, and, connecting them by a wire, examined the intervening liquid with a large reading glass, previously placing a strong light on the other side of the cell. I did not, of course, expect to see the molecules of water moving; but I thought that I might possibly perceive the indications of a current by the movement of floating particles in the solution; and, in order to make this more conspicuous, I dropped small pieces of thread, &c., attached to little bits of sugar, between the plates, and watched their rise on the sugar dissolving. As far as I could judge, the threads came up perfectly straight as regarded their course, showing no tendency whatever to be drawn towards either copper or zinc. The tiny particles in the fluid also sank and rose as perpendicularly as though nothing were going on; and, whether the current was passing or not appeared to make no difference to them. Having placed a galvanometer in circuit, I could test this. The usual bubbles appeared on the copper, and the zinc was slowly dissolving: but nothing else was apparent. While watching the exhibition of the electrical microscope at the Crystal Palace a few days ago, it occurred to me that, if a similar experiment to mine were thrown on the screen, something *might* become visible under such enormous magnifying power; and at the close of the lecture I suggested it, but the lecturer did not seem to think it possible. I should have thought it feasible: and, therefore, send this letter to see what others of "ours" think of it.



CENTRIFUGAL MACHINE, SHOWING INSIDE.

I suppose such an idea has been thought of; but no work that I have makes any mention of it; nor, I presume, has there been any microscopic power previously available equal to the one referred to above? I never remember seeing the experiment tried in the Polytechnic times, though I often saw their microscope; perhaps it was privately tried and nothing resulted, so it was thought useless for a public exhibition. **B. Harcourt.**

STORAGE BATTERIES AND ELECTRIC CURRENTS.

[22375.]—An expression of opinion as to the various accumulators now in the market, from those who *have used them*, would be of much assistance to those who, like myself, are only waiting for the improvement of these inventions to adopt them.

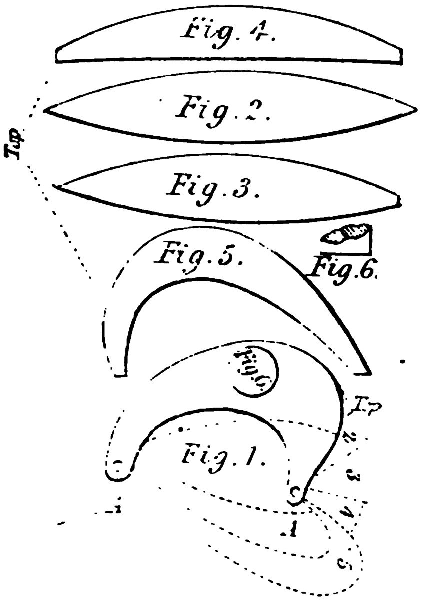
Besides the original Planté, there are the Faure-Sellon-Volckmar, the Elwell-Parker, and the Brush "B. T. K." system, the Barnett, used at the Paddington Station; and probably others. For my own part, I should be greatly obliged to anyone who will describe the advantages, and the faults, of each of them.

As to "current," I have found in the last volume of the *Electrician* a definition by Mr. Sprague, which seems to give one holding ground, at last; he terms it "the rate of flow." Well, that is intelligible; water in a ditch, and water in a river, may each be flowing at three miles an hour, though the volume of one will be very different to that of the other. Then the next thing will be to learn what, in "current," is the analogy to volume of water. Is it to be "density," or "high and low tension"? Or shall it be called E.M.F.? which I now begin to believe means neither more nor less than "difference of potential."

By the way, there is also a letter in the *Electrician* from Mr. Varley, protesting, as I ventured to do, against the multiplication of units and terms in electrical science. **Antares.**

HOW TO MAKE A SELF-SUPPORTING EAR TRUMPET.

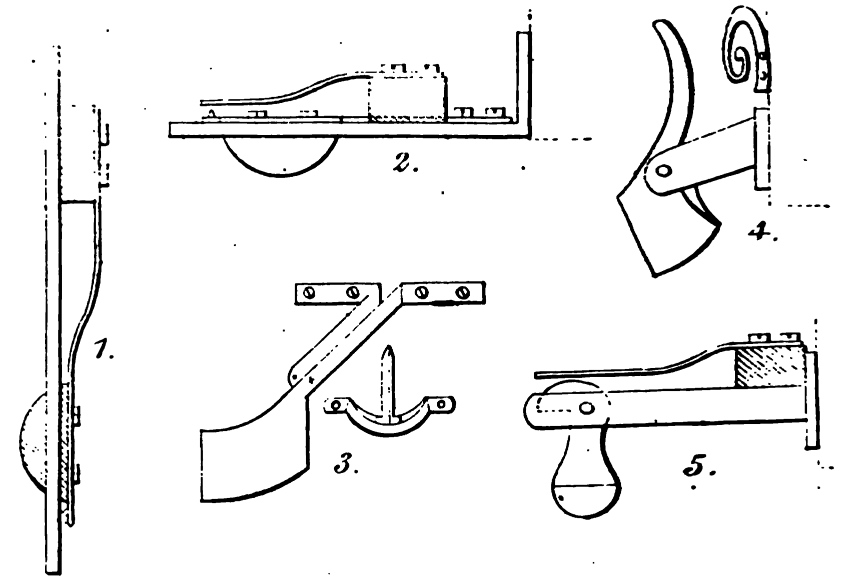
[22376.]—SEEING a letter a short time ago in your paper relating to a simple ear trumpet, I now venture to give below instructions for making a simple, yet effective one. I contrived this instrument so as to fit on the ear and support itself, thereby leaving the hands at liberty. I will now describe it as briefly as possible. Procure a piece of tin about 8in. square, cut out five pieces, as shown in the following cuts: then punch the two holes, A A; get a piece of square elastic (such as is used by boys to make that destructive little instrument—the catapult); stretch it from A to A, and secure each end. I use elastic so as to fix it on with more ease and comfort than would be the case if string or cord were used. Now, round off the inner edge with solder, or wire it, so as not to cut the ear; bend Fig. 2 to fit the outer edge of Fig. 1, and solder it, then fix and solder Fig. 3; then proceed in the same manner with Figs. 4 and 5. The edge of Fig. 5 should be rounded, as in the case of Fig. 1. The rough edges where joined are then filed, and the crevices filled with solder. Cut a piece from a cork (as in Fig. 6), and glue it on to Fig. 1. This rests against the temporal bone, and steadies the trumpet, which may now be considered complete; but japanning outside and a coat of flesh-coloured paint inside greatly improve its appearance.



M. Y. C.

DOOR CONTACTS.

[22377.]—JUDGING from recent queries and correspondence that some of our readers are interested in the subject, perhaps I may be allowed to offer them rough sketches of five typical forms, varieties of which are now almost as numerous as makers themselves. No. 1 represents the class in which contact is maintained, whilst the spring is at rest in the position shown, but is broken by pressure on the stud. This is the form ordinarily used for thief alarms; it is mortised into the joint of a door between the hinges, or between the beads of a window sash, so that when the door is opened or the sash is raised, the bell continues to ring until they are closed again, or the circuit is broken at the controlling switch. No. 2 is an ordinary form which is fixed upon the door frame in such a way that the door, in passing strikes against the stud, and, pressing it up, makes contact between the two springs. The bell, in this case, rings when the door is either opened or shut; but as there are, unfortunately, more people who open a door than who close it after them, it often happens that the door gets pushed nearly to, without being actually shut, and coming thus to rest just under the contact, the bell keeps on ringing until someone stops it by opening or shutting the door entirely. As the too frequent repetition of this kind of thing was good neither for the tempers of the inmates nor the endurance of the battery, other forms were devised to obviate the inconvenience by causing the bell to ring whilst the door was in the act of opening only. Of these, No. 3 was probably the earliest made in England; the two springs were fixed just sufficiently above the door for it to clear them in passing, a small pin of thin oval section being fixed upon the door in such a position as to press gently against the right-hand spring as the door opened, deflecting it sufficiently to bring it into contact with the other. The curve of the broad end of the spring, and the oblique direction of the edges of the pin were so nicely adjusted to each other, that when the door was closing, the pin passed on the left-hand side of the curve as near as possible without touching it. No. 4 is a now well-known French pattern "*pied de biche*; like the others, it is fixed above the door, which, on opening, brings the upper end of the drop into contact with a spring behind. No. 5 represents another class of single-action contacts originally designed, and made by a contributor to the "E. M.," though long since copied by our ingenious neighbours across the Channel—its mode of action will be obvious. Another type of door contacts I have not referred to, as a sketch of one of them was given by a correspondent at p. 478 (52739): in these, one contact spring is fixed upon the door, and the other on the frame in such a way that they touch each other in passing—they are, of course, double action, as in No. 2. Those of our readers who desire these things to work satisfactorily should bear in mind that they are fixed in positions where, of all others, they are most exposed to draughts, bringing in any quantity of dust and damp; all points of contact should, therefore, be carefully platinised, whilst some kind of protecting cover is also desirable. The ingenious amateur will soon, however, discover for himself that in practice there are many other little points which need attention in the fixing of even such simple things as these, in order to insure that they shall continuously work without a chance of hitch at just the very times when most relied upon.



R. T. Lewis.

AMATEUR MUSICAL INSTRUMENT MAKING.—VI.

[22378.]—I NOTED five sizes of key cups in the table, in part 4, as being necessary; but of course seven or eight sizes would make the instrument look neater, for it will be noticed that the cup outside is about 5 mill. larger than the sounding hole, if the key is between No. 1 and 6, and the smaller keys have the cups about 4mill. larger than the holes they cover.

To make cups, take, say, five pieces of round steel and fit them to run as lathe centres; turn up to proper diameter, and round the ends like the cup Fig. 19 (each being nearly 1 mill. less than the outside sizes). An iron plate about ¼in. thick is drilled with about a dozen holes, the largest being 19 mill. and the smallest 8mill. They can be then reamed out with a taper widener 8in. long, 19mill. at one end, and 8mill at the point; thus each hole can be made a certain amount larger than its neighbour, and by turning the plate two sizes are obtained; the edges on each side are then carefully smoothed with a countersink drill. The metal being softened, is cut into squares, and the corners cut off, double the size of the required key. It is then placed on a plate, over a hole about 1 mill. too large, and the steel punch above it, which is then gently struck with a hammer till the outline is depressed about 1mill. The hole next smaller is then oiled and the metal driven further by the punch; the edges of the key are then trimmed close by shears and the punching proceeded with, till [illegible] and size are correct. The key is then put on a wooden pin, turned up and polished in the lathe; it is then cut off to length, say with an edge of [illegible] outside, which is afterwards slightly burnished inwards, and serves as a good hold for the pad. Drills are required of various sizes for pillars, &c. and the best for this work are Fig. 25 and 35. The former is the Archimedean, and should have a [illegible] metal spiral 7in. long; the latter is for holding in the vice, and is used by jewellers. Drill Fig. [illegible] is for general metalwork, and may be made of umbrella frame steel. Fig. 27 is a wood countersink about ⅜in., used for smoothing holes. Fig. [illegible] is a generally useful flat drill for wood. Fig. [illegible] is used for boring pillar holes and flattening the wood round the edge to allow the pillar to screw close up. All these are used with the Archimedean drill. Figs. 30, 31, 32, 33 are used with drill Fig. 35. Fig. 30 is sharp along the edges only, and is used for boring out small tubes or widening holes. 31 is used to roughly face up the edges of pillar heads; 32 is for facing up angle pillars, and consists of a small rose cutter, jammed on a round shank, removable when required. Fig. 33 is used to widen the end of a tube when it is desired to solder another tube to it, the other tube being tapered to enter it a little way, the soldering arrangement being shown in Fig. 36. B is a wire fitting the bore of tubes C D, to be joined at A by blowpipe. After soldering, the drill (Fig. 30) is run through to clear the bore. Fig. 37 shows how a shank is held on a key cup while being soldered; the tongs consist of a pair of engineers' inside calipers held together at F by a metal strap shown at G. The method of drilling the soundholes is shown at Fig. 38. H being the body, lying on a block of wood G, and held down by a wood bar K, by two screw nails, the drills used being sharp centre-bits shown at Fig. 34, driven by a joiner's brace; about seven sizes are required altogether.

Springs may be made from sewing needles and flat springs from old watch spring. The former are broken near the thickest part retaining the point end, are then put on a thick metal tray over a lamp, and cautiously heated till they are of an even blue colour, taking plenty of time and rolling them about to insure regularity. The thick ends are then slightly flattened with a hammer and the spring slightly curved like Fig. 39. Flat springs should not be made of too thin material, as breadth does not make up for thickness; the watch spring should be slightly heated to reduce temper where the hole is bored for screw, the end nicely filed and bent to lessen friction (see Fig. 40). Flat springs are best for keys that require to be kept shut, especially if they are large; needle springs do nicely for rings or keys that are small or remain open. The tone of every wind instrument depends on the tightness of the pads or keys, and the execution of a player is greatly improved by the nice working of key-springs; generally the smaller travel a spring has, the longer it lasts, and the more comfortable it feels to the player. A spring requires its least power after a key is raised, and its greatest power to keep a key shut. This cannot always be obtained, but the nearer it is approached, the more perfect will the instrument be mechanically. This is effected by having the spring exactly the proper length, that, when the key is opened, it slides below the centre or joint; when the key is shut, it recedes from the centre, and thus obtains leverage—consequently strength (see Fig. 41). It will thus be apparent that time spent in adjusting springs is not lost when the principle is understood. Screw plates are required for making taps, to screw pillar heads, &c.

and for this purpose, perhaps, two will be required to fit all the screws from Figs. 12 to 16. As to the screw-foot of pillars, Fig. 21 and 22, they are usually put on by the maker, but are generally defective; therefore, a plate or screw-dies to fit them is a convenience. A tap for screwing the holes in the body may be made by soldering a pillar to a rod and filing the screw into a square. Taper screws can be made on pillars by using die-pincers, having the pillar held in a chuck, and running the lathe the reverse way. Rings may be made two ways: first, wire can be made into the rings and soldered, turned up, and then soldered to the shank; this, however, is easy only after practice. It will be found best to bore and cut the rings out of solid metal, No. 11 or 12 B.W.G. = ·12in., then turn up in the lathe and solder to the shank (see Fig. 42.) Shanks are made from wire, 5 B.W.G. = ·22in.; it is flattened a bit (see Fig. 44), and then hammered into a slot in steel block, 43, which alters it to shape 45, 46, and is then cut off at the dotted line; eventually, being shaped by a file into Fig. 42, then soldered to the ring. Before treating of each key in detail, we now return to the body and complete the bell, &c., left off at end of Part 2. It must be noted that the body enters into the top end of bell, which is formed into a socket, bound by a metal ring, and in order to assimilate the narrow bore with the taper of the bell, the body must be widened at foot, up to two cent., above the middle of key No. 1 (see Fig. 6); this meets or continues the general curve of inside of bell. The bell measures, on the C clarinet, 9·6cent. long, including both rings; at the upper ring the diameter outside is 3·1 cent. At lower ring the wood is 6·8 cent. For B flat the length is 10·5cent. The wood outside at upper ring is 3·5cent., and at lower ring the wood is 7·3cent. The inside of both bells have the same taper, and may be cut by the same tool, which reaches, as before stated, up to the first hole. In the C clarinet, the tool will go up 12cent. and in the B flat it will go 13·5cent. This cone measures in length 13·5cent.; width at top, 14·5mill; width at bottom of socket (4·5cent. from top), 22mill. At 7cent. down it is 28mill.; at 9cent. down it is 34mill.; at 12cent down (bottom of C bell) it is 41mill.; and at 13·5cent. down it is 54mill. If, then, 4mill. of wood are allowed at each side, then these sizes plus 8mill. will be the outside sizes, except at the socket and lowest ring as mentioned above. To make the bell: a piece of wood, proper size, is chosen, leaving plenty of room, and bored through with a ¼in. drill; it is then roughly turned up, and inserted in a large wooden cup-chuck; the inside is then cut out with a turning gouge, near the size, it being finally finished with a steel scallop or cutter the size of the cone; this may be made by turning a piece of wood to the size, and being cut through with a saw, a steel cutter is inserted and secured by pins, after being dressed to the outline of curve. The wood bell is then removed from chuck and placed on another fitting the internal space; the outside is then turned, finished, and varnished. The socket cut out and both rings fitted. The large ring may be made like an ordinary ring, and secured by pinning; but the following is better and stronger. Take a strip of German silver, 11mill. broad and 22 B.W.G. thick, solder the ends and form into a ring about the correct size; a very narrow groove, the size of this ring, is then cut by the lathe, in hard wood about 8cent. deep. The ring is inserted, and the 3mill. beaten inwards, forming an angle section; the outside and end of this ring are then turned up and the metal softened; it is then put on the bell and the flange beaten into its place, the ring is then finished up and polished. Fig. 47 shows the ring fitted on bell before closing. Fig. 48 shows section of the work complete.

9th Feby., 1884. **Vulcanite.**

LATHE WITH FRONT SLIDE.

[22379.]—I believe Mr. Carre's plan—to make the top V on the inner side—is, on the whole, better than placing it as figured in my diagram, as it will tend to keep up the truth of contact between saddle and bedpiece. There should be a hollow or space below the path of the fast V of the saddle, so that chips or turnings might fall in this, and be easily swept away without interfering with the contact faces of the slides. I am glad our valued instructor, "J. H.", intends to devote a little attention to this form. With this and the pattern for a suitable gap piece, he will render his admirable papers on the lathe complete. **Orderic Vital.**

OVERHEAD LATHE.

[22380.]—Will the author of "How to Make a Cheap Lathe" kindly add to his invaluable article a description of patterns for overhead motion, suitable to strong 5in. treadle lathe, for driving drills and cutters for metal? **Sailor.**

UNLIMITED LIABILITY LATHE.

[22381.]—It was with great curiosity that I read the article on p. 507, by "O. J. L.," upon the "Unlimited Liability Lathe."

In the paper "O. J. L." professes to show how any ordinary lathe can be converted into one in which articles can be turned in size out of all proportion to the maximum size for which the lathe was originally designed to accommodate.

Now, does he do so? I think not; nor does he say that *he has turned anything by means of the converted lathe.*

I think we ought to have a little more data to work upon before altering a lathe in the manner suggested, because although it may look well upon paper to the originator of the idea, it may not work so well practically.

It is quite against my experience to find it possible to turn (even the circumference only) a superfices with a diameter of 2ft. upon a 3in. lathe, I question whether there would be power enough in the treadle, band, &c., to even make the work revolve, and we must not forget that great power is required as well, for shearing or cutting the material.

Ordinary turning requires the assistance of a rest to support the tool, as the work would when rotated (if the tool be not supported) cause the tool to descend in a tangential direction, and ultimately leave the work, without producing any result as far as turning is concerned. The work when being turned by the usual method, is fixed vertically, and at the point of contact of the tool and the periphery of the circle; tangents drawn from that point would be perpendicular, or nearly so, and the rest being placed under the tool, and horizontally, it overcomes the natural gravitation of the tool, and the tendency of the circle to drive down the tool tangentially and away from its correct position. Ergo, "a rest" is an absolute necessity to support the tool when turning.

Does "O. J. L." comply with that imperative condition in his proposal for unlimited liability? It will be seen that he does not.

By his plan the work rotates in a horizontal plane, and all tangents to the circles will be hori-

[illegible]ontal, and the rest will [illegible] in a lower parallel plane, and not at right angles to the work [illegible] fore, when operations are [illegible] the tool be fixed, and it is not proposed to be [illegible] in the article), the tool will [illegible] in a tangential direction, and along the face of the rest; the result would be about the same as trying to turn without a rest. Of course, some of the evil effects might be overcome by a projection upon the top of the rest (provided always that the work can be got to revolve). "O. J. L." does not propose any addition to the rest for that purpose.

I should like to have a little more said about turning the face of the circle by the suggested plan. "O. J. L." seems to be (discreetly) silent about that, to me, very difficult part of the work. Has he turned a 2ft. circle on a 5in. lathe.

In the sketch the disc of the chuck is shown fixed upon the boss eccentrically to the axis of the boss. Why is that? Also, in the drawing, the band is shown passing down from the guide pulley under the rest, and thence to the back of the wheel, and there is not shown any portion of the band round the front of the wheel.

Perhaps "O. J. L." will explain this, as I cannot understand the action of the band under these conditions.

W. A. Barber.

THE FRONT SLIDE LATHE AND MILLING.

[22382.]—I AM a good deal smitten with the design suggested by F. Carre, in your issue of last week. When he says, "the bracket for rest could be made to slide vertically," he proposes a pet idea of mine, which I have been too busy to work out, and which I think might prove a valuable one. I propose to have a strong vertical slide in front, where he has written "bracket": the slide should carry the cross slide of the rest, which would be drawn firmly down by the raising and lowering screw, into a kind of shoe, when doing plain turning, so as to give solidity. The slider-plate of this cross slide having in it the circular groove for the T-headed bolts securing the upper part of slide-rest, should be made as large as possible, so as to form a table to which to bolt work to be bored, which could then be most easily adjusted level with the centres by raising the vertical slide. This table would also receive milling centres or work to be milled, the cutters being placed on the mandrel nose.

There may be objections to the plan which I do not at present see; but we shall all be wanting to do milling soon, and this plan appears to me far better than a detachable vertical slide rest. I commend the idea to Mr. Bear, and hope F. Carre will persevere with it.

Tunbridge Wells. **F. A. M**

MOLLER'S PROBE-PLATTE.

[illegible] HAVING lately received from Mr. Baker some beautiful samples of Moller's latest work—viz., Probe-platte mounted in phosphorus, monobromide of naphthaline, balsam and dry, a few remarks may possibly interest some of your readers.

With regard to strength of resolution, I think the [illegible] carries the palm; it is closely run, however, by the phosphorus; next comes the monobromide, [illegible] balsam. The phosphorus, like all dry [illegible], has an unkempt appearance, but [illegible] has the special charm of combining [illegible] strength of resolution with the well known [illegible] balsam. When speaking, in the following [illegible] as a fine test, I mean merely as [illegible] test, with oblique light.

[illegible] I should choose, for really testing [illegible] with axial illumination, would be [illegible] Triceratium favus (in- [illegible] No. 1; Navicula lyra (one of the [illegible] I have ever seen), No. 3. P. litto- [illegible] formosum, No. 60.

[illegible] further I ought to mention [illegible] compare some of the diatoms [illegible] with the same kind in [illegible] with hardly any exception, all [illegible] in phosphorus, as also in [illegible] only some are.

[illegible] having seen a selected dry [illegible] worth looking at. I do not [illegible] should be so; it is, however, [illegible] who have had a large, if not [illegible] myself, have stated the [illegible]

[illegible] of obtaining a dry A. [illegible] tipping until you get [illegible] valves are exceedingly [illegible] a laborious process to [illegible] between a 60 [illegible] early 100 balsam [illegible]

[illegible]

[illegible] long. striæ, good [illegible] very similar to N [illegible] ·0041, striæ 63·5 [illegible]

No. 8, P.P.—Nav. Rhomboides, length ·0059, same as T.P. [illegible]: length ·0075, striæ 60 in ·001, resolved by [illegible] N.A. ·64 = 80° and [illegible] N.A. ·64 = 79°.

No. [illegible], P.P.—Nav. Rhomboides, length ·0043, similar to the English Rhomboides on slides commonly labelled Amici's best striæ (estimated) 75 in ·001.

No. 11, P.P.—Nav. Crassinervis, length ·00287, cannot resolve it with any dry lens, striæ finer than in N. crass.: T.P. 3-4-30, length ·00359, striæ [illegible] in ·001, which wide-angled dry lenses resolve.

No. 15, P.P.—Gram. oceanica, small, but coarser than usual, length ·00192, ¼ N.A. ·77 = 100° resolves it. The same on T.P. 2-1-15 is longer—[illegible] ·04, striæ very much finer: 88 in ·001, important diatom as limit of resolution with dry lenses.

No. 28, P.P.—Nitz. sigmoidea, fine test for ¼ of ·80 N.A. ·4[illegible].

No. 31, P.P.—Nitz. curvula, well-known test, length ·0046, evidently identical with Nitz. sigmatella: T.P. 2-5-10: length ·0042, striæ 89·6, both beyond the resolving power of dry lenses.

No. 32, P.P.—Nitz. obtusa, length ·003, the limit for dry lenses on the P.P., resolution just beginning with ¼ N.A. ·88, dry 1/6 N.A. 1·0 masters it. Very different from Nitz. obtusa, T.P. 2-5-12, length ·00[illegible], striæ 99·5 in ·001, resolved by ¼ N.A. ·77 = 100°.

No. 33, P.P.—A. pellucida, long and coarse, ·0046 beyond the power of dry lens, striæ (estimated) 92 in ·001.

No. 34, P.P.—A. pellucida, small and very fine; ·00283, slightly smaller than A. pell. T.P. 2-6-6; length ·00329, striæ 100 in ·001.

No. 35, P.P.—A. Lindheimeri, fine test for dry lenses of moderate apertures: striæ (estimated) 70 in ·001.

A dry ¼ N.A. ·81 = 108° will resolve all except Nav. crass., Nitz. curvula, the two Amphipleuras, leaving the Nitz. obtusa doubtful.

Edward M. Nelson.

MICROSCOPICAL—AN OFFER.

[22384.]—I SHOULD be glade to forward a few Podura (Lepidocyrtus curvicollis) to any one wishing to study their beautiful scales.

Joseph Wall.

Woburn House, Woburn Hill, Green-lane,
Liverpool.

A NEW MOTOR.

[22385.]—As a great number of readers of the MECHANIC are interested in the tricycle, and any suitable motor which could easily be made applicable to the same would be looked upon as a great advance upon the present mode of propulsion, I copy the following remarks from the *Tricyclist*, Dec. 25th, 1883, to which I would refer our readers to a more lengthy description than can be given in this letter. A company is formed to work the invention of a Mr. Sturge. The following are the inventor's statements as to its capabilities.

"This invention is calculated to entirely revolutionise most descriptions of light traffic, and be a means of opening up an entirely new as well as great and important industry, equal in many respects to steam and electricity."

That is clear enough, in all conscience.

The pamphlet continues—

"Of the various means of locomotion hitherto employed, none can compare with Mr. Sturge's system for speed, simplicity, and economy, and although the invention is not at present applicable to heavy vehicles such as railway carriages, tram cars, &c., the field for its use is still sufficiently wide to render it one of the most important improvements of the age.

"The striking advantages of Mr. Sturge's invention which give to it absolute and undisputed superiority over any other existing invention or contrivance, may be briefly summarised as follows:—

"1. Propelling power is provided, and no personal exertion is required beyond guiding the carriage.

"2. Any rate of speed up to 15 miles an hour is attainable.

"3. The length of the journey is immaterial.

"4. The carriage will travel up hill as easily, and almost as quickly, as on a level road.

"5. The power applied is specially adapted for rough or heavy roads.

"6. The apparatus is most easily regulated and controlled, and the carriage can be guided with equal facility and stopped instantaneously.

"7. The propelling power is contained in a very small compass, and is of no appreciable weight.

"8. The cost of construction is exceedingly moderate, from £2 to £3 being sufficient to adapt the apparatus."

The Editor concludes thus:—

"For should this motor fulfil the claims made for it, the question of aerial flight will be very soon solved, and the roadster tricycle will die out before Mr. Blank's aeroplane vehicle, with a record of 50 miles per hour, driven by a motor of no appreciable weight."

I should like to hear something more of this important invention: or are we to class it with the electric engine or Keely motor?

Geo. S[illegible]

8, Hawthorns-street South, Sunderland.

GLASS DISCS FOR REFLECTORS.

[22386.]—MR. CAPLATZI (22348) thinks my plan of getting glass discs for specula rather [illegible] and tedious. I grant it looks like this at first sight, but it serves my purpose better than any other I have tried, and I have tried many. To give Mr. Caplatzi an idea of what he ought to aim at in improved methods of procedure, I will explain how I go about getting, say, for example, a 6in. disc. I go to a glass-seller's shop in the town, where there are many such, I have no doubt, in London and other large towns. I order a piece of glass [illegible] and 1in. thick. This the tradesman [illegible] some of the plate-glass makers, and gets for me at 1s. 6d. The edge is nipped round—rough, of course, but still round as a whole, and perpendicular as a whole on its sides. This disc I take to the glass-cutter, with a circle of tin cut accurately round 6in. dia., and my curve gauge, both [illegible] scribed; he then rounds the edge smooth to the 6⅛in. dia.; the rough side of the disc he [illegible] curve, and chamfers off the angle all round top and bottom, so that the curved [illegible] face is exactly 6in. dia., and as round as the piece of tin. All this he has always charged me 1s. for: thus I get a 6in. disc ready for grinding for 2s. 6d. The dishing out the curve by the glass-cutter saves a lot of hard work, as it only takes me about one hour's work with rough emery to bring the surface to the curve of the tool, and ready to begin with my finer emeries. This will give Mr. Caplatzi an idea of what price he ought to be able to get the work done for, and at what price he ought to be able to sell the discs, edged and dished out, to the amateur, made from his stock of glass, and with the improved methods he will adopt, since a [illegible] others I get in proportion only cost me [illegible] And if he can find out some better mode by which he can sell them at a cheaper rate, I hope he will let us know how he does it, in the same way as we all are willing to help him. Many amateurs, I am sure, will be glad of the information [illegible] beginning with a 6in. or 9in. disc; above that size [illegible] discs have to be used. **H. A. Wassell.**

Addenbrook-villa, Love-lane, Stourbridge.

[22387.]—THE method described by Mr. [illegible] on p. 520 is that which I have reason to [illegible] would be adopted by glasscutters. The simplest form of putting it into practice would be to take a strip of sheet copper and bend it into a circle, brazing the ends or securing them by a double rivet of this shape —. That is now to be pressed on a block of soft wood, which is either provided with a handle or with a spindle and pulley, by which it could be driven from an ordinary grinder's wheel. I do not know whether emery and water, or emery and oil would do the fastest work: but the emery and oil would leave the cleanest edge. The only difficulty is starting. Firm pressure without a slip must be kept up until the copper has worked a little trench, then the speed can be increased. **Nun. Dor.**

PEN AND INK DRAWINGS FOR THE LANTERN.

[22388.]—THERE is much truth in the saying that "there is nothing new under the sun," as, although the following process is perfectly original as far as I am concerned, it doubtless will have occurred to many others: but, on the other hand, I believe that there are many of your readers who would be benefited by the publication of this method of preparing magic-lantern transparencies:—

1. Procure some cardboard of medium thickness, and cut this up into slips of the required size, to act as carriers. Next, in each of these pieces make an aperture of the required size and shape for the "picture."

2. Procure some of the thinnest paper possible, which will stand ink (i.e., without running). This paper should be of even texture, and free from watermarkings and other lines. Ordinary tissue paper will do for pencil drawings, but these do not look so well as those executed in ink, and ink will run if used on ordinary unglazed tissue paper. Having obtained the required paper, it is convenient to cut it up into pieces of the required size—i.e., somewhat larger than the apertures in the cardboard.

3. In addition to the above, the only desiderata are:—(i.) Ink (I use ordinary black writing ink but any other medium of sufficient opacity will do). (ii.) A fine etching or mapping pen. (iii.) Glue. (iv.) Gum. (v.) Canada balsam dissolved in benzol. (vi.) A camel-hair brush or two.

Having made a drawing, or taken a tracing, on one of the slips of thin paper, gum it, in position, over the aperture in one of the pieces of cardboard (being careful to let no gum fall on the drawing itself). Unless care is used, some difficulty may ise in getting the paper evenly stretched over the aperture in the cardboard, but, after a few trials, this is easily accomplished. Having got the drawing evenly arranged, glue another of the cardboard carriers on to the one holding the "picture" (of course, the apertures in the two cards must exactly coincide), and set aside to dry, weighting it to prevent "warping." When dry, paint *both sides* of the thin paper over with Canada balsam dissolved in benzol; this "clears" the paper, making it almost as transparent as glass, except where the lines of the drawing are. The balsam dries in about 12 hours, and then the "slide" is ready for the lantern. If the object is alone cleared, and the rest of the paper left opaque, the pretty effect of a luminous object on a dark ground will be obtained, and some drawings of medusæ, infusoria, &c., which I have prepared in this way, look very well.

I have no doubt, although I have not tried it as yet, that this process will answer for coloured pictures, though I am afraid the balsam will have a tendency to make aniline colours run.

I do not claim that this process supersedes pictures on glass, but it is certainly an easier and very much cheaper process, and all who try it will, I am sure, be pleased with the result.

In conclusion, I may say that I have not tried these slides with the oxyhydrogen light lanterns, and it is just possible that ordinary writing ink may not be sufficiently opaque for so powerful an illumination, but I think Indian ink would answer perfectly. **Fred. Farrow.**

Ardwick, Manchester, Feb. 16.

THEORY OF THE EYEPIECE. — V. — SUMMARY OF FORMULÆ — ON FURTHER APPROXIMATIONS FOR THE DISTORTION, AND GENERAL REMARKS—PROPOSED EYEPIECE.

[22389.]—It will here be convenient, for the sake of reference, to collect together the principal formulæ which we have obtained. We have, then, for the dispersion—

$$\frac{\sec.^2\theta\,\delta\theta}{\tan.\alpha} = \frac{b}{f_1 f_2}\left(2d - f_1 - f_2 + \frac{df_1}{b}\right)\frac{\delta f_1}{f_1} \quad ..\ 1$$

for spherical aberration—

$$\text{sp. ab.} = \frac{f_2^2 A_1}{(f_2 + c - d)^2} + A_2 \quad \ldots\ldots\ldots\ldots\ 2$$

for distortion—

$$D = \tfrac{1}{2}\frac{v^2 h^2}{f_1^3 f_2^3}(f_1 + f_2 - d)^2(f_1 + f_2) \quad \ldots\ldots\ 3$$

The two first of these are general, and apply to any ray whatever and any pair of lenses, b and c being the distances from the first lens, and the point where the ray meets the axis before and after refraction respectively. Where the ray, after second refraction, passes through the focus of the eye lens nearly, $b = \frac{f_1(d - f_2)}{f_1 + f_2 - d}$, by means of which eqn. (1) becomes—

$$\frac{\sec.^2\theta\,\delta\theta}{\tan.\alpha} = \frac{(d - f_2)^2 + f_1 f_2}{f_2(f_1 + f_2 - d)}\,\frac{\delta f_1}{f_1} \quad \ldots\ldots\ldots\ 4$$

and (2), treated in a similar manner, gives—

$$\text{abn.} = \frac{v^2}{f_2}A_1 + A_2 \quad \ldots\ldots\ldots\ldots\ldots\ldots\ 5$$

(3) is already adapted to eyepieces, and in it as well as in (5) v is approximately the distance of distinct vision, or more exactly $= \Delta - e$, where Δ is the distance of distinct vision of the final image, and e the distance of the eye from the eye lens.

In (2), for parallel rays, c becomes f_1. To compare the results with the equivalent single lens, (4) gives—

$$\delta\theta^1 = \frac{(d - f_2)^2 + f_1 f_2}{f_2(f_1 + f_2 - d)} \quad \ldots\ldots\ldots\ldots\ldots\ 6$$

and lastly (3), will give—

$$D^1 = \frac{f_1 + f_2}{f_1 + f_2 - d} \quad \ldots\ldots\ldots\ldots\ 7$$

$\delta\theta^1$ and D^1 being the ratios produced by the pair to that of the equivalent lens. All these have been carefully tested, by seeing whether they will give the result which ought to be given by a single lens, such as the eye lens alone, if there were no other, of the equivalent lens, &c.

They will furnish an easy method of comparing the aberrations, &c., of the instruments in common use with any other arrangement that might be proposed. Thus, in a Huyghenian, if we were to reverse the order of the lenses, by which it would become a positive, the distortion will remain the same as it is while the dispersion is only one-third.

Again (to which I would draw attention) if we place the *curved* side of the eye lens towards the eye, instead of the flat side, as is usually done, we shall find that the ratio of the spherical aberration in the first case is to that in the latter in the ratio 5 + 21 : 5 + 81, or 13 : 43. It will be asked, Why, therefore, is it not done? Let us see; and this will introduce us to the necessity of taking into account sometimes further approximations than have been used for the foregoing formulæ. In fact, it will show that we must in some instances take into account the *thickness* of the lenses; but this will in general be only necessary for a near approximation in the case of distortion.

If we examine an object, such as a square of an inch, divided into nine equal squares, with a plano-convex lens of, say, an inch focus, we shall find that when the flat side is turned towards the eye, the distortion, and also the colouring, in consequence of the unequal distortion of coloured rays, is much less than when the curved side faces the eye.

On the other hand, if we examine a *test object* with the same lens, used as a simple microscope, and focus it carefully with rackwork, we shall find (such at least is my own experience) that the details are sensibly better seen towards the centre of the field when the curved side is towards the eye. This is owing to the spherical aberration being so much less, the proportion being 7 : 27 of what it is when the other side faces the eye. But when we come to estimate the distortion, which, as we have seen, varies inversely as the cube of the focal length, we shall find that it is *less* when the flat is turned towards the eye—that is, away from the object or image from which the rays proceed; for when we take the thickness into account, the principal focal length is different, according as the rays fall upon it on one side or on the other. Thus, if t be the thickness of the lens at the axis, f^1 its focal length when the latter is taken into account, and f when it is neglected, we have $f^1 = f + \left(\frac{\mu - 1}{r}\right)^2\frac{t f^2}{\mu}$ (Parkinson's "Optics," p. 93), in which t and f must be measured in the same direction for all kinds of lenses, and r being the radius of the surface which the rays first fall upon, the focal length is greater when the curved surface is turned towards the object, and therefore the distortion is less.

By placing the flat side, therefore, towards the eye, we reduce the distortion in a Huyghenian, though at the expense of the sp. ab., and thus the general field will be better with the usual arrangement, though the definition near the centre wil not be so good, owing to there being less sp. ab. when the flat side is towards the object.

The arrangement generally used, therefore, is that which gives the *least distortion*, but not the least aberration. And this seems to bear out what was said in a previous letter, that in an e.p. the correction chiefly to be aimed at is that of the distortion.

This, it would seem, may theoretically be much better effected when one of the lenses is *concave* and the other convex; in fact, when such is the case, we may find such an arrangement as will render the right side of any two of the equations (1) (2) (3) equal to 0; but not all of them simultaneously.

Proposed Eyepiece.—We may now offer the following for consideration. The first lens plano-concave, the second plano-convex, with focal length *numerically* equal to that of the first, and placed at a distance from it equal to twice the focal length of the eye lens, the curved side of each of them being turned towards the eye, and I would propose to call it an "undistorted eyepiece," not because the distortton is absolutely 0, but because it would seem to be much smaller than that of those in use, and I propose in the next letter, which will conclude the subject, to give some further explanations. **W. G. Penny.**

Errata in Letter IV.—In line 17 of (column 1) from bottom of page, for Gr write G^r. In 6, from top of col. 2, for Br write B^r. In line 22 from bottom, col. 2, for P^3 write F^1.

HARMONY IN NATURE.

[22390.]—Since Keppler "yielded to the secret fancy to write a book," nothing has been proved to move or vibrate in nature inharmonious to its own proportion or that of its surroundings, at least not for any length of time. This is, of course, quite natural, for if we suppose, for argument sake, that in any part of the universe a body were to move or vibrate inharmoniously to its surroundings, it would either be overpowered, or, if strong enough in its movements, must ultimately overpower and direct the movements of other bodies, and so create a new law. This latter hypothesis seems not very probable. From the results of experiments I have made, it is quite clear to me that from the movement of a planet, down to the vibration of molecules, there is no difference excepting the distance and velocity: all follow the same law. Much has been done since Chladni founded our acoustical knowledge: yet, with all that, we have not come to the root, the law. The brothers Weber supposed that the results of all their experiments emanated most likely from one law. They were earnest in their supposition, for all and every movement or vibration of any body or matter follows one law. This I shall prove conclusively at a future day. So far, all seems clear to me; but the organic life presents great difficulty in my study, and the following question has repeatedly come uppermost in my mind—namely, is organic life parasitic on nature, and follows to a certain extent its own law? I feel disinclined to accept this view, because, if it were so, a state of things as above mentioned must ensue. The organic life must either conquer the law of nature, or *vice versâ*. My study has now been for some time in the direction to find whether anything is growing inharmonious to the law of vibration, or to its own constituent parts. Having lately come to a (for me) as yet inexplicable fact—namely, that the sound of the step of the left foot is a semi-tone higher than the sound of the step of the right foot. I have found it in man and horses without an exception. To hear a pair of horses trotting on a wooden road is quite a musical display.

My object in writing this is to see whether our anatomical subscribers can give a reason for this apparently stringent harmony, for which I crave their kind condescension. **J. H. Schucht.**

SUPERFICIES OF THE OCEANS OF THE WORLD.

[22391.]—Allow me to call your attention to an error in the estimate of the areas of oceanic surface in your last issue, Feb. 15th, p. 514, in the article "Superficies of the Oceans of the World," by Dr. Otto Krummel, by Göttingen. These estimates are throughout quite evidently incorrect. This is, I presume, due to incorrect translation (I have not Dr. Otto Krummel's work to refer to); but we find the entire estimate of oceanic surfaces, which is the correct addition of the separate estimates, to be 231,915,950 square miles, and this is obviously much greater than the surface of the entire globe. It may be most satisfactory to give the generally-accepted dimensions, which will show the evidence of the error.

Polar diameter of the globe	41,848,380ft.
Greater equtorl. dia. 194° 23′ to 14° 23′ East Greenwich	41,852,864
Smaller equatorial dia. opposite above	41,834,896

From which we may calculate the mean diameter to be about 7,912 miles. The expression for the area of the surface of a sphere is $4\pi v^2$, when

π = 3·14159 nearly
v = 3,956 miles radius

Therefore the surface is 4 × 3·14159 × $(5,956)^2$ = 196,650,700 miles.

The area of terrestrial surface, as stated in your article, 34,354,950 square miles appears to be correct, by which the oceanic surface would be 162,295,750 square miles. **Wm. F. Stanley.**

THE RECENT COLLISION AT STOCKPORT, AND CONTINUOUS BRAKES.

[22392.]—A collision occurred on the 15th December, at the L. and N. W. station, Stockport, between a passenger train from Crewe and a train of empty carriages which were being shunted into a siding.

The circumstances have been inquired into, and Col. Rich's report is published. There are, however, a few points to which attention should be specially directed. The collision was in a great measure due to the omission of the signalman in Stockport No. 1 cabin to give the Edgeley Junction signalman the "warning signal." This omission led the driver of the Crewe train completely into a trap. We will now consider the brake power upon which the driver had to depend. The train was made up of an engine (No. 1,745) not fitted with any brake; a tender with a hand brake only; three vehicles fitted with Clark and Webb's chain brake, supposed to be under the driver's control by means of a cord; three more vehicles with the chain brake under the control of the guard; and two Great Western coaches without brake power.

When the train approached Edgeley Junction the signals were "on," but afterwards taken "off" for it to proceed. The Stockport "distant signal" was next sighted, and as it was at "danger" the fireman at once attempted to apply the tender hand brake; but this failed, in consequence of the crank on the brake shaft giving way.

The driver reversed the engine, pulled the cord of the emergency chain brake, and opened the whistle; yet in spite of all his exertions the chain brake failed to stop the train, and allowed it to run 1,040 yards past the signal, through the tunnel, and come into collision with the empty carriage train. Nothing is more easy than to blame the engine-driver—and, of course, this has been done by the advocates of the chain brake; but looking at all the facts of this case, I arrive at a very different conclusion. In the first place, the driver was undoubtedly led into a trap by the Edgeley Junction signal being lowered at a time when the line was blocked at Stockport; and secondly, what more could a driver do than apply all the brake power under his control, and reverse his engine?

Your readers are well aware that the chain brake has frequently failed and caused collisions and accidents [illegible] that I [illegible] great [illegible] with an efficient [illegible] without difficulty [illegible] entirely [illegible] the companies [illegible] railway [illegible] with a [illegible] engine [illegible] the [illegible].

Clement E. Stretton.

Saxe Coburg-street, Leicester, Feb. [illegible].

THE WESTINGHOUSE BRAKE DOUBLE COUPLING.

[illegible]—The ordinary single Westinghouse brake coupling is well known to your readers, and was illustrated in my letter in XXXV., page [illegible]. One pipe throughout the train and that a required for the efficient working of the brake, but sometimes from having sustained damage, or in account of not having been replaced when worn out, the indiarubber couplings between the vehicles burst, the result being that a train may be delayed or stopped unexpectedly. To avoid this inconvenience the plan shown in the annexed diagram has been devised. The ordinary single pipe is unscrewed, and the double pipe (Fig. [illegible]) substituted, and screwed to the main iron pipe by means of the projection (A). The box (B) contains a ball-vall (C), which is free to close the passage to either branch. When the train is charged with air the pressure is equal in both hosepipes; but should one burst the ball (C) is instantly forced to that side, thus preventing the escape of air from the main train pipe and the consequent application of the brake.

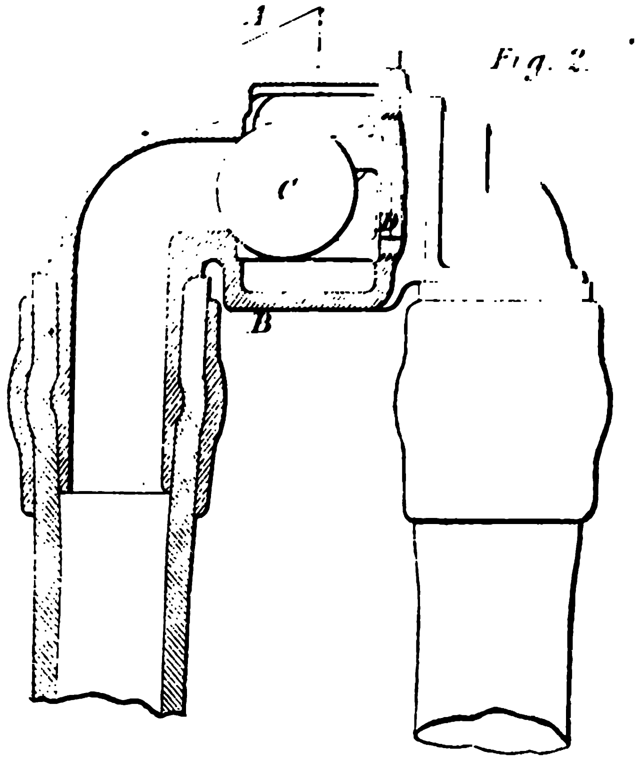

Fig. 2.

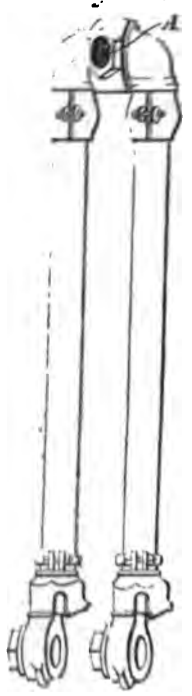

Fig. 1.

To insure both hosepipes being charged with an equal pressure, a small groove (D) in one of the ball seats allows air to pass. When the same pressure exists in both hosepipes the ball will be in equilibrium, and drop from its seat into an intermediate position.

It is probable that all the railway companies will not agree to adopt the new coupling. It is therefore advantageous that the new double coupling can be used with the single pipe hitherto employed, as it is quite sufficient to unite only one of the two couplings to another vehicle, the second being left open. In such a case the coupling to the right hand (when looking towards the end of the vehicle) should be coupled; otherwise, there would be waste of air through the groove (D).

Clement E. Stretton.

Saxe Coburg-street, Leicester, Feb. 8th.

CONCERNING LOCOMOTIVES.

[illegible]—I fear the quotation which Mr. Grey makes from my former letter, will not assist this important discussion. I maintain, Sir, that the speed at which an engine can exert its full tractive force is a matter for experiment; but, most certainly, I did not even make, or think of making, such an absurd statement as [illegible] Mr. Grey [illegible] pressure in cylinders [illegible]. There are [illegible] great [illegible] that [illegible] engine [illegible] experiment. It is a [illegible] what an engine [illegible] they frequently [illegible] companies [illegible] details of the actual working of new engines; [illegible] such details were made, does any [illegible] weigh [illegible] water [illegible]. It is well known that there are engines now at work which have been designed for working certain traffic, yet when tried they fail to perform the duty, yet the [illegible] would prove that they ought to do so. The water space between tubes and around the fire-box, the space in the tubes, diameter of blast pipe, are matters which some seem to think unimportant; but these are just the points which may spoil a design, and to which Mr. Grey does not even refer. If he wishes to enter into a discussion upon these points I shall be happy to give him the benefit of my experience, which extends over 30 years on several railways and in locomotive builders' works.

Historian, M.I.M.E.

Erratum.—In letter on "Ice-fractured Shell," p. 520, last line but two. For "pressure principle" read "pressure per inch."

The Ship-Railway across Mexico.—The ship-railway across the Mexican Isthmus of Tehuantepec is being pressed forward in earnest. The survey of the isthmus has been completed under the care of Mr. Van Buskirk, an eminent American civil engineer. A route with even more moderate gradients and cuttings than were expected has been adopted, and the works have been commenced. Mr. J. B. Eads, C.E., the builder of the great steel bridge across the Mississippi at St. Louis, and whose improvement of the Mississippi navigation has opened up New Orleans to ships of the deepest draught, is now in London concerting business arrangements with shipowners and others, and the probability is that the ship-railway will come under British control, financially and otherwise. Several gentlemen eminent in and in connection with the shipping world are taking the subject up warmly, as this route will shorten the sailing distance between Europe and the North American Pacific coast, including, of course, the British possessions, by more than [illegible] statute miles, and [illegible] miles less than the Panama route.

REPLIES TO [illegible]

*** In their answers, [illegible] fully requested to [illegible] and number of the query [illegible].

[illegible]—[illegible] as I said in [illegible] iron is exactly the same [illegible] by air, but [illegible] length of a [illegible] traversed by a [illegible] "L. F. H." [illegible] between two [illegible] tions. Take, for [illegible] tions per second [illegible] corresponding to [illegible] condensations spread [illegible] and the wave-length [illegible] owing to the greater [illegible] number of condensations [illegible] 17,000ft., and hence the [illegible] would be 531ft., which [illegible] C in iron. As [illegible] of the particles [illegible] much is known; [illegible] Rayleigh has been [illegible] must be exceedingly [illegible]. For air about [illegible] at by his lordship [illegible] audibility of a whistle [illegible] second.—Wm. John Grey [illegible]

[52282.]—**Screw Press.**—[illegible] get a greater pressure than [illegible] pose with the (three per inch [illegible] has, then he might do the [illegible] of turns, by using a screw [illegible] pitch (say two per inch). [illegible] available strength of the lad [illegible] to give the last turn of the screw [illegible] not advise him to alter the screw [illegible] haps the following arrangement [illegible] not, if he will write again, [illegible] shall be glad to do my best [illegible] come them. Let him use the [illegible] and make the block that carries [illegible] it can be moved up and down [illegible] treadle; but it must have a [illegible] rangement, that is, it must have a [illegible] to catch in suitably arranged teeth [illegible] falling, and also to take the pressure [illegible] when it is raised. The method [illegible] then be as follows:—The mould [illegible] be at the bottom of its stroke; [illegible] in the required quantity of clay. [illegible] step on to the treadle, which would [illegible] the mould up towards the stamp [illegible] of the lad had no more effect, the [illegible] into one of the teeth and prevent [illegible] the screw would then have to be [illegible] the stamp down into the mould to the [illegible] tent, and then back again to its orig[illegible] the lad would depress the treadle, releas[illegible] and allow the mould to drop down ag[illegible] get the pot out.—A. Sugden.

[52390.]—**Dynamo.**—To "W. H. [illegible] "W. H. E." mistakes my query, as [illegible] of my F.M. is about ·75 ohm, not [illegible] says; resistance of armature ·5 ohm [illegible] Would it benefit me putting wire on the [illegible] on the legs on each side of F.M. [illegible] much as I can get on close to the pole[illegible]—Dynamo.

[52399.]—**Governors (U.Q.)**—I had [illegible] the above query until I saw it in the [illegible] Queries, or else I would have tried and [illegible] it before. I will give you a rule to find [illegible] of arm of a Porter's or weighted govern[illegible] the number of revolutions, and find the [illegible] a simple governor; then add together [illegible] of the revolving balls, and twice the wei[illegible] centre weight. Multiply the sum by [illegible] found, divide the product thus obtained [illegible] of the revolving balls. The quotient [illegible] will be the height of a weighted [illegible] We will suppose we want a governo[illegible] volve 288 times per minute, the weig[illegible] balls to be 5lb. each, and the centre wei[illegible] 30lb.; required the length of arm [illegible] Then [illegible] the required height [illegible] Dewsbury.

[illegible]—**Gout.**—This question [illegible] Readers of the "E. M." are now [illegible] that gout and rheumatism are diseases [illegible] cess of urate of soda in the system, and [illegible] rational cure is to get rid of this. T[illegible] be fresh be formed whilst you are [illegible] that you already have. Abstinence f[illegible] and alcoholic drinks prevents urate [illegible] forming, whilst the drinking freely [illegible] and the use of hot baths will help [illegible] system of it. Drugs should [illegible] destroy the blood corpuscles, and [illegible] with the urate, which are more difficult of than the original waste, and so prolong se.—T. R. ALLINSON, L.R.C.P., &c.

.]—**Finishing Surfaces.**—Thanks to for his short reply. I beg to say that they done on a milling machine, as I am ac- l with the capabilities of milling machines, been accustomed to working them and other s for some years. Should be very much for a full reply, as I think it would benefit s well as myself. Shall wait patiently, and meone will give the necessary information as possible.—L. T. B.

0.]—**American Organ.**—"Organon" is when, as at p. 475, he makes me say I can eeds as well as anybody. I never made such ard statement. Ready-voiced reeds by the nerican makers are not in the market; there- re out of the hunt. When I said I succeeded ing reeds equal to those I can buy ready , I, of course, alluded to those which are in rket. These latter, I have reason to think, ly set as near as the eye can judge, and are ied and individually corrected in an instru- Are we to consider it an impossibility for a nan, whose daily work is among metals and anism, to do the same thing—that is, copy the and twist from reeds known to be well voiced? writers in "ours," especially Mr. Fryer, to me to make far too much mystery of this g business, apparently taking it for granted beyond the amateur's powers. I refer now ordinary diapason tone, and not to fancy solo Mr. Fryer rightly supposes my experience to ry limited; but as I never miss any oppor- y I may have of examining reeds in good s, and will undertake to accurately reproduce nd and twist, I suppose I may be allowed at a chance of ultimate success. Now, as to the nce of the board upon the tone. Both your spondents seem to consider one board as good other, allowing each to be sound and well to correct scale; they would, therefore, I me, engage to make an equally good organ any such board. But if a given reed sounds ently when placed in various positions on the board, may there not be differences in the it gives when placed on other boards, which possibly be made of other qualities of wood? xperience, if it is short, teaches me that not only oundboard, but in a less degree, the parts of ase also, influence the tone for good or bad. ve," in one of his incomparable letters in a volume, recommends a correspondent to split rd up, and boil the pot with it, if he cannot the reeds speak properly upon it. What does mean, if not the possibility of getting hold of l board? "Organon" raises an imaginary ulty as to telling which are good. The only I can suggest would be to clamp them on a lchest in a temporary manner, and try them a well-voiced set of reeds. I, for one, should ad if "Joiner" would tell us what he knows the soundboard affecting the tone of the ument. Also, his present opinion of the nt of 16ft. tone desirable in an instrument d be welcome. If I remember rightly, his manual has three rows of 16ft. As "Organon" es to know how my board is built, I may tell it is an ordinary three-row, 16 and 8ft. rows to ack and the 4ft. facing front. The half-row 6ft. solo set, set right at the back, and having well. The "Queen's Model" is the same osition, with, I believe, the addition of another solo set. Therefore, I think "Organon" has unduly hard upon me, seeing I erred in such company; but I value his letters none the less at.—J. E. FLOYD.

549.]—**Unfermented Bread.**—In answer to E. L.," I use only unfermented and un- ed bread. The wholemeal flour is simply d with a little salt and water only and kneaded a dough; this is put in tins and then baked. bread is firm and keeps well; I have eaten it three weeks old. Being close-grained, it res thorough mastication, which means proper ivation, and so good digestion.—T. R. ALLIN- L.R.C.P., &c.

654.]—**Point of Greatest Transverse in.**—The calculation on p. 500 only gives the nce of the centre of gravity of the mass from upports, and the point f is not necessarily the of greatest strain.—J. S. C.

654.]—**Point of Greatest Transverse in.**—"Querist" says that I have not answered uery. I say, in reply, that his query admits of nswers, and that I have sent one of them. Querist" place a solid block of stone, accord- the conditions of his query. Then, with the est deflection of the beam mentioned the t of 4½ and 5½ tons is then on two points at 4ft. and 6ft. from each end of the beam.— ER, Accrington.

61.]—**Tar in Greenhouse.**—It is only it is fresh or gives off fumes that it is in- s to plants. Go over it with a hot iron, rubbing well about, and while still soft, dust over slack lime, cinder dust, sand, and anything else that will form a coating. Why did you not paint as others do?—BEGONIA.

[52673.]—**Children Sleeping with Aged Persons.**—This query cannot be satisfactorily answered. Some say that the old being cooler than the young abstract some of the heat from the young, and so cause ill-health. This fact seems to support their view: in childhood the pulse is quick, whilst in old age it is slow. A rapid pulse means increased heat, whilst a slow one means diminished heat. We also know that a certain heat is necesstry for life, and what lowers that heat must decrease or lessen life.—T. R. ALLINSON, L.R.C.P., &c.

[52674.]—**Photo-Etching.**—I think I understand what "F. H." means by etching on copper plate "by the aid of photography." He means a photograph of a line drawing transferred to or photographed on to a copper plate, and the lines protected by varnish, rosin, &c., while the other parts of the copper plate are eaten away by acid. If I m correct, I think he will do well to read up what has been published in connection with photo-zincography, which will give him an idea of how to proceed with copper. I know of no other process of etching copper by the aid of photography.—NUN. DOR.

[52676.]—**Printing Paperhangings.**—The art of printing paperhangings is sufficiently explained in such works as "Ure's Dictionary." If any special point is indicated by the querist as needing elucidation, I will help him; but briefly, paperhangings are made thus: the colours are made by mixing suitable pigments with size; the ground colour is applied by means of a brush, the design by means of wooden blocks engraved to suit, three or more being required to complete anything but the very simplest designs.—NUN. DOR.

[52684.]—**Platinised Silver.**—All that "Gulliver" has to do is to drop in the platinum salt until the silver plate is thoroughly covered with a black coat. I am unable to tell him how much platinum chloride is required per sq. foot, but he can easily ascertain, and need not waste a hundredth of a grain.—NUN. DOR.

[52690.]—**Patent Armatures for Dynamo Electric Machines.**—Legally, you cannot make any patented article; but practically you can, for the simple reason that no patentee would think of bringing an action for infringement unless you interfered with his business. So far as the armatures of any machines of the kind are specified, it would be interesting to learn how many of them are valid patents; but if the Gramme patent is not extended this spring, anyone will be free to use and sell machines constructed according to the specification of Gramme and D'Ivernois, dated 1870.—NUN. DOR.

[52693.]—**Watch Jobbing.**—I am sure that if this querist will only look through his back volumes, he will find the information he requires—not once, but several times.—INDEX.

[52695.]—**Electric Bath.**—There is not much difficulty about fitting one up; but to get it to cure even general debility will be a puzzle indeed.—ANAS.

[52705.]—**Spiral Wood Turning.**—This is done in an ordinary lathe, without slide-rest. The querist should see a turner at work on twisted pillars and table legs, and he might discover how it is done; but it requires a deal of practice. Something about it can be found in back volumes. J. T. M.

[52709.]—**Fire Alarm.**—"Inquirer" apparently wants a fire alarm that can be sounded at one spot, to alarm an area which he does not specify. If steam is always ready, there is nothing better than a powerful whistle or roarer; but it might answer if a strong bellows is used instead, with either a fog-horn, a whistle, or a reed organ-pipe. Failing these, there is nothing better than a bell.—ESSAR.

[52711.]—**Decoration of Jewellery.**—This query is rather a curiosity. What sort of jewellery is it that is to be decorated by means of baths of alkaline plumbates, &c.?—ESSAR.

[52715.]—**Steam Launch.**—"Nun. Dor." remarks on p. 456 that a boat 12ft. by 3ft. will only make from 6 to 8 miles per hour. It would be interesting to know the maximum that this or any vessel is capable of doing, and I should be glad to see how he finds this. Therefore, a boat 24ft. by 6ft. would, say, make 12 miles per hour at its medium rate of progress; and one, say, 300ft. by 96ft. would give 192 miles per hour; and, say, such a vessel made the voyage to America, it would reach there before it started, all things being favourable—a consummation I think that would be very much appreciated, especially by our cousins over the water. Putting joking aside, will someone say what would be the maximum speed to be got out of any of the vessels that run to America, providing they were engined and boilered to their utmost capacity, allowance being made for all contingencies? The answers to these questions being such theoretical and far off from the point. "Nun. Dor." has often made some funny dogmatical remarks in this paper, and seems to think that anything he gives vent to is a settler, and should be accepted as such. People will get egotistical in letter writing until they are brought up occasionally, so I hope he will go into the subject, and show us the why and wherefore of these things.—P. W. R.

[52719.]—**Flooring for Sheds.**—May I suggest that asphalte would be as useful as anything?—T. R. S.

[52720.]—**Telephonic Patents.**—I should think there cannot be much doubt that they are patented in Australia. I don't know, but I should think the cup-and-ball instrument can be used in this country; but Bell's is the only receiver.—S. M.

[52780.]—**Bath Heater.**—"H. H." cannot heat his water quickly by his present system; but if he will look on page v., Feb. 15th, he will find there advertised a water heater which can be made to heat the water at any speed. In the best water heaters, it takes about 1 cubic foot of gas to heat 1 gallon from 50° to 105°; and in the average as usually sold, it takes about 2 cubic feet to do the same work. If, therefore, "H. H." wishes to heat 40 gallons in any specified time, he will need from 40 to 80 cubic feet of gas supplied to the burner in the same time, depending on the class of water heater selected.—T. F.

[52790.]—**Sewing Machine.**—I must thank "W. E. W." for his reply; but it does not give the information I wanted. I am quite aware that it is much cheaper to buy a rotary hook than to make one; but there are numbers of readers who would rather try their hands at making a hook, even if it cost eventually thrice the price of a bought one. To anyone who has a lathe and accessories such a task cannot be one of extraordinary difficulty, if he has only reliable diagrams to work by. These and the requisite information I trust "W. E. W.," or some other reader, will be willing to give.—LOCK-STITCH.

[52792.]—**Steam Launch.**—In reply to "N. R. C." as to the size of engine, I have been looking at a launch about the size I sent sketch of, and I took the measure for "N. R. C." or any other reader it may interest. There are two cylinders, 4in. bore and 7in. stroke, inverting cylinders, direct-acting crank made of 2in. bar; propeller shaft made out of 1¾in. bar; propeller, two blades; boiler from grate bars to top, 2ft. 10in.; diameter, 2ft. This is outside measure. Inside shell leaves 2in. water space all round, and 11in. on the top, but there is a dome on the top of boiler 14in. diameter and 12in. high, steam pipe bolted on top of dome with flange boiler; chimney comes through centre of dome, projecting through about 3in. for strong sheet iron to fit on; propeller 21in. diameter.—THOMAS THOMPSON.

[52792.]—**Steam Launch.**—In reply to "H. H. H.," if a 15ft. launch will do, the sketch I sent will still do to go by: you will only have to make each part to suit yourself. You can easily tell how many ribs you want. For a 15ft. launch, 6in. apart, you will want about 28. You can put them 4in. or 5in. apart if you are not particular to a few ribs, but they are never put closer than 4in. apart. To know what pitch to bend the ribs marked D, nail frame ribs marked *m* temporarily to stem and shaft post on both sides of boat, beginning with top pair, stretch them apart with lengths of any kind of wood (to remain in until all the ribs D are fastened on ribs *m*) 4ft. for about 8ft. length of boat, then let them come closer together gradually towards stem and shaft post; treat second pair the same, only they must be a little closer together—say 2in. or 3in.; do the same with third 2 or 3 closer than second, and the same with fourth pair. Put all four pairs of *m* frame ribs equally apart between top rail E and keel A, then notch bits out of stem and shaft post to let ends of *m* ribs in level, all middle D ribs for about 7ft. or 8ft. length of boat will be same pitch, about the shape of a U, but the rest of ribs at each end of boat where D ribs come narrower, they will be about the shape of a V. If you find any trouble in bending them, draw both ends of each rib in the shape of a half-circle, tie with a strong band, and put them all in a copper or cask of scalding water for an hour, then take one out at a time nail it to *m* ribs and keel. By this treatment you can bend them any shape you like. It will now be ready for planking. For a 15ft. launch I would not have the propeller less than 16in. in diameter. As to the number of blades the propeller should have, it is hard to say: some have 2, 3, and 4 blades both in launches and large steamers. You might try three blades. They will not always tell you at the foundry how to make the pattern so that it will leave the sand. It will cost twopence per pound casting.—THOMAS THOMPSO

[52862.]—**Chemical Problem.**—Neither Grey nor "Student" seem to have noticed the problem, which is one given at the Hono [illegible] Art Department. [illegible] for the hydrogen required [illegible] is two-thirds of 282·34 [illegible] whereas the hydrogen added [illegible] vols. There must [illegible] in correcting the proof [illegible], I expect.—C. J. Wood-[illegible]

[illegible]—**Feed Pump.**—In cases where the [illegible] is any fractional part of a foot, [illegible] a decimal by dividing the [illegible] denominator, so with the stroke [illegible] should have the decimal number [illegible] = ·06. Then, 4 × 4 = 16 × ·034 = [illegible] × 30 = 18·452 or nearly 18½ [illegible] I had not noticed your query, [illegible] Economiser." I am afraid I cannot give [illegible] information, for all I have the charge of the same, I never had any trouble with the caps or covers. I should try to get them off by the following:—Thoroughly clean round the outside edge of cap, and then get some turpentine put well round edge for, say, a day or two before you want to get them off; then screw off the nut and fasten a piece of twine or wire to the thread of the bolt to prevent bolt from dropping inside of pipe, and keep tapping the cap with the hammer. Of course, you could lower the bolt inside of pipe, and insert a lever inside of bolt hole, and remember that perseverance overcomes difficulties.—FIRER, Dewsbury.

[illegible]—**Cough Cure.**—"David" evidently knows nothing of physiology, nor has he perhaps seen the article in the "E. M." of Dec. 21, 1883, copied from the *Lancet* (on coughs), else he would not ask the question he does. "David" wants a universal remedy for coughs of every kind. This is an impossibility, considering that a cough may be due to one of many causes. It may be due to acute or chronic lung disease, to inflamed throat, to a diseased heart, to an aneurism pressing on the laryngeal nerve, to some irritating food in the stomach, &c. This should show "David" the uselessness of his inquiry, and instruct him that a cough is only a symptom of disease elsewhere. Coughs can be stifled, and patients as well, and coughs can be stopped, but the breathing made so difficult that the cure is worse than the disease. So [illegible] stick to your trade. It takes men [illegible] medicine to use drugs properly in [illegible] You may do much mischief in [illegible] kind efforts.—T. R. ALLINSON, [illegible]

[illegible] **Governors.**—The size and weight of [illegible] depends upon the nature of the [illegible] to transmit the agency of the [illegible] throttle-valve. An increase in the [illegible] gives the governor more [illegible] the throttle-valve; but it [illegible] way affect its working. I [illegible] balls you mention, one is [illegible] or weighted, [illegible] are with ample. I [illegible] with the governor [illegible] Dewsbury.

[illegible] **Governors.**—[illegible] weight of the balls [illegible] the least. Each [illegible] a number [illegible] particle of [illegible] attached to [illegible] overcome the friction [illegible] on the steam [illegible] thereto. Though [illegible] centripetal force, [illegible] in the same proportion [illegible] Browne, C.E.

[illegible] **Lights.**—The angle is [illegible] light, [illegible] not forget what I [illegible] is not always [illegible]

[illegible] **Pressure.**—It is difficult [illegible] from the [illegible] atmosphere is only [illegible] quantity of [illegible] by doing [illegible]

[illegible]

[illegible] on the dynamo, the current of which it is measuring, it is, on the contrary, wound with a wire of as low a resistance as possible; indeed, the conductor often consists of a simple broad strap of copper that offers an inappreciable resistance to the passage of the current, in front of, and parallel to which, is pivoted a small magnetic needle, which tends to turn at right angles to the current, and as the angle is directly proportional to the quantity of current, it is easy, after once finding how far a current of known strength turns the needle, to calculate the strength of an unknown current. An instrument of this class has, however, one disadvantage—viz., as the needle becomes after a time less magnetic, it is necessary to occasionally take a fresh reading with a current of known strength, to recalibrate it. There is another class of instrument which is constant, and in this form a suspended conductor is hung at right angles to a fixed conductor, through both of which the current to be measured passes; the current tends to turn the suspended conductor into the same plane as the fixed conductor, and the dynamic force it exerts by this tendency is measured by the torsion of a spring, and from this the strength of the current is calculated. Such an instrument is Siemens' electric dynamometer.—ELECTRICIAN, Dublin.

[52927.]—**Watch Work.**—After you have taken your watch to pieces, try the pillars and see that they are not loose; examine the pinions and see that they are not loose, and especially the escape-wheel, as that is very often loose. See that there is no bur in the lever; rub it over with your burnisher. Mind that your staff pivots come far enough through the jewel-holes and round the tops of the pivots; examine the jewel-holes and endstones. I should think the stopping is caused by the suspension and detent not working when being wound up. Mind that the inspring does not rub on the barrel cover, and the bottom of the barrel does not rub on the centre wheel; try all the depths and endshakes, and see they are all upright. If everything is nice and free, I don't see what can stop it varying in action. —DUM SPIRO SPERO.

[52943.]—**Electro-magnets.**—Thanks to the willing hands who replied to my query on p. 504. I do not want nature to alter her system for my bit of apparatus; but a more general practical knowledge and compliance with the laws of nature among the English people would not hurt them. I confess my ignorance of the existence of residuary magnetism in electro-magnets, and regret to learn it is inevitably a law of nature or nature's system, as "Sigma" terms it—a thorn in the flesh for which there is no remedy. It is the holding power only I want to utilise, and not the attractive power, and for the wellbeing of my apparatus the residuary magnetism is highly pernicious. I note the magnets should be made of soft iron, say, Swedish iron, and thoroughly annealed. The tinning or deposition of copper on the poles of the magnets deteriorates the useful effect.—C. B.

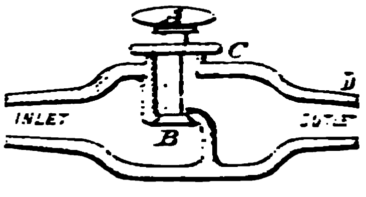
[52950.]—**To Violinists.**—If your hands perspire much, you had better use acribelle or metallic E strings, and steep your hands several times daily in a saturated solution of alum: but possibly the breakages may be caused by your nails being too long. Do not be discouraged at your inability to stretch the little finger: it is a difficulty experienced by all beginners, and can be overcome by practice and perseverance. I would advise you to work diligently at the following exercise on the E string, both with detached and legato bowing, very slowly at first, but increasing in rapidity as proficiency is attained: E B, F sharp B, G B, A B, A B, G B, F sharp B, E B. This exercise may be repeated a fifth lower on each of the other three strings. I will gladly give you any further help in my power, and would remind you that Tartini scarcely touched the violin till after 30 years of age, and that Spohr's best pupil began at 21.—WAR.

[52959.] **Beer in Scratch-brushing.**—Try strong soda-water, common washing soda, or nice soapy water rather warm. I have used both for three years past, and find them answer very well; use a cork to procure froth.—DUM SPIRO SPERO.

[52959.] **Beer in Scratch-brushing.**—The replies to this may be all right; but I think the mixtures would be no improvement on beer. The London jewellers generally use size. I have for several years used size made from the best light-coloured glue, made so thin as to have no smell when it is cool, and to run freely on to the brush. I put 2oz. or 3oz. in a saucepan with a quart of water, and simmer over the gas stove. It is ready in 10 minutes, and if too thick to run freely add warm water. It must be very thin, or will clog when cold. You will find this quite free from objectionable smell, such as beer and vinegar have.—J. F. A.

[52961.]—**Hand Water Tap.**—Thanks to "T. F." and "Sigma" for replies; but their suggestions do not meet my requirements. The hand-tap must be such as I can (having only one hand at liberty) lift, use, lay down, lift and use again a good few times, perhaps in the course of ten minutes, the flow to cease instantly wh[illegible] use. An ordinary mouth blowpipe w[illegible] purpose admirably if there could be fixed [illegible] perhaps some kind of valve which could be [illegible] trolled with thumb or finger so as to [illegible] ously turn on and shut off the flow of water [illegible] it at will.—ARNOLD WARBURTON.

[52961.]—**Hand Water Tap.**—W[illegible] constructed on the same principles as th[illegible] at some of the railway station lavator[illegible] your requirements: By pressing a small [illegible] front of tap the stream of water can be [illegible] at will. (See sketch.) A, small knob of brass [illegible]



piece of brass wire screw in [illegible] end of wire small leather washer is [illegible] slight pressure on A the water passes [illegible] B: C, gland for packing: D, tap ends [illegible] on rubber tube.—WILLIAMS.

[52962.]—**G. W. R. Engines.**—55 Queen [illegible] single-wheel double-framed inside-cylinder [illegible] engine, having 7ft. drivers, 17in. by 24in. cylin[illegible] It was built at Swindon in September, [illegible] the designs of the late Mr. Joseph Armstrong [illegible] is stationed at Paddington. Nos. 483 and [illegible] 490) are 6ft. four-coupled passenger [illegible] having inside cylinders 16in. by 24in. The[illegible] built at Swindon in 1869. 55 is a four-coup[illegible] passenger engine, having driving wheels [illegible] diameter, was built at Swindon in Octobe[illegible] and is stationed at Reading. [illegible] four-coupled passenger engines, were bu[illegible] Wolverhampton in 1864, and most of them [illegible] been recently rebuilt there. 55, Queen, [illegible] 481—490 are of the late Mr. Joseph Armstr[illegible] designs. 55, Queen, has been lately improved [illegible] Mr. W. Dean, now having plain splashers [illegible] brass dome. It also has the new type of [illegible] adopted by Mr. Dean.—J. E. SPENCER.

[52963.]—**Weight of Coaches.**—The L. and N. W. Railway Company's six-wheeled coaches weigh respectively 10 tons.—J. E. SPENCER.

[52971.]—**Antimonial Lead.**—Dissolve a portion of the alloy in as little nitric acid as possible with the aid of heat. When all is dissolved, boil and then add a large excess of pure water, which will ppt. the antimony as an oxide and filter. Evaporate the filtrate to less than the original bulk, and treat again with water: this will ppt. all the antimony that remained in the solution after first treatment with water. The two precipitates washed together, may then be dissolved in HCl and a piece of clean iron immersed in the solution will ppt. the antimony in the metallic state. The filtrates and washings mixed together may be evaporated to dryness, and the lead weighed as nitrate ($Pb2NO_3$). This may be reduced to metallic lead by fusion with charcoal in a Hessian crucible.—AN OLD APPRENTICE.

[52980.]—**Crescent Moon.**—I once saw the "young May moon" under 30 hours old, the prettiest imaginable tiny thread of golden light. It was in the year 1833, taking my first journey up to London by the North Devon coach. We had a three o'clock dinner at Taunton, then my friend and I rode outside as far as Salisbury. The evening was exceptionally clear and summerly—thus it was that I could watch the western sky. Reference to an almanac for that year will verify my statements; but the impression on my memory is that the moon changed early on Monday afternoon, say, near six o'clock, and I saw it on Tuesday evening, soon after nine o'clock, at 29 hours old. I believe that Tuesday was the 19th of May. I have frequently seen the moon under 40 hours old—never but the once under 30.—H. O'B.

[52980.]—**The Crescent Moon.**—If the point of this inquiry lies in the comparative rarity of favourable opportunities for astronomical observations generally, owing to "our wretched climate," the instance recorded by your correspondent may possibly be deemed "noteworthy"; otherwise I think it can hardly lay claim to such distinction. After the turn of the year, and during the early spring months, the young crescent moon has considerable northerly declination, as compared with the sun, and may then frequently be observed much within the interval after conjunction, which he describes—viz., 38 hours. In the present case her early appearance was favourably influenced by her being at the time near the point in her orbit of her extreme north latitude, and under similar circumstances I once succeeded in obtaining a view when she was less than 22 hours old. In Drew's "Manual of Astronomy" an instance is given of an observer having noticed the waning crescent near conjunction in the morning, and the waxing crescent in the evening of the following day. I need scarcely say that this could hardly have been observed in our latitude.—W. T. N.

[52980.]—**Visibility of the New Moon.**—It is not often that the new moon can be seen with the naked eye when less than 38 hours old, the conditions being generally unfavourable. But occasionally in the spring months the narrow crescent of our satellite may be distinguished much earlier than this. On March 30, 1881, I saw the new moon at 7h. 10m. when she was only 20 hours 38 minutes old; and on June 4, 1875, at 9h. 10m. when only 22 hours 49 minutes old. I am not aware that a "younger" moon than that of March 30, 1881, has ever been observed in this country. The Rev. S. J. Johnson, in his work on "Eclipses, Past and Future," p. 116, says:—"It is a curious point to notice how soon we can see the crescent of the moon after new. In the spring a casual observer may catch sight of it, when very clear 24 hours afterwards, but I have hardly ever detected it younger than this. A case is related of the moon's thin crescent being seen early one morning before sunrise and after sunset next day. But in the torrid zone Vespucius is said to have seen the moon to the east and west of the sun on the same day." I know of few more interesting sights with the naked eye than is afforded by the extremely delicate crescent of the moon when between one and two days old.—W. F. Denning, Bristol, Feb. 11.

[52981.]—**Bichromate Battery.**—The solution should remain unchanged and good for any length of time when not in use. Only when (after more or less work) it becomes of a greenish colour is it spent and useless. The failure of the light might have been due to the polarisation of the battery plates, or to local action in the cells owing to defective zinc plates. I should recommend "M. A." to examine the zinc plates of his battery, which, probably, need reamalgamation.—Student.

[52982.]—**Gramme Dynamo.**—Size of wire for field magnets, No. 16; weight, about 5lb., or 1¼lb. on each division above and below. For armature, about 4lb. No. 20, in 16 sections of ¼lb. each. This will absorb rather over one man-power, say ¼ horse, and ought to light well four Swan lamps of 10 c.p. Please publish result, and oblige all.—S. Bottone.

[52982.]—**Gramme Dynamo.**—You do not say whether you wish to wind your machine as a series or shunt dynamo; but you will find a series machine most useful for general experimental purposes. Wind A with No. 20 double s.c., and put as much No. 18 on F. Ms. as will just equal the res. of A. You can find the quantity required for F. Ms. after you have wound the A. by looking at a table of resistances, and remember that the res. of A. is equal to half the weight of wire wound on. About four 5 c.p. lamps; about one man power; sixteen, the more the better. When you have it finished send result.—W. H. E., Coventry.

[52986.] — **Lightning Conductors.**— The Houses of Parliament are protected by conductors of copper tube, some 2in. in diameter, and ⅛in. thick, fastened together by solid screw plugs and coupling pieces secured to the building by metallic staples. This was the recommendation of Sir W. Snow Harris in 1855, and was carried out by the Board of Works at a cost of £2,314. The plan was costly and somewhat faulty, on account of the large number of joints. These conductors were recently tested and repaired by a competent electrician If "Conductor" will write to 11, High-street, Walthamstow, E., further information will be willingly given by—Samuel Vyle.

[52991.]—**Metal Turning.**—I think you will find much, if not all, the information you appear to want, in a series of articles on "Tools" which will shortly be issued.—J. H.

[52994.]—**To S. R. Bottone.**—Prime cost, home made, about £5. Hourly cost to drive it, by the cheapest battery that will do the work, comprising attention, 6d. My judgment advises—*Don't.*—S. Bottone.

[52995.]—**Pressure of Sea Water.**—A cubic foot of sea water weighs about 65lb., hence, for every foot of descent there is a pressure of ·451lb. per square inch over and above the pressure due to the atmosphere on the surface. The querist can surely calculate the pressure at any required depth from the above figures.—Wm. John Grey, Elswick Science School.

[52995.]—**Pressure of Water.**—As the pressure of water on the bed of the sea is only another term for the weight of the water on a given area, and as the quantity of water above us increases as we descend, it follows that the pressure increases in proportion to the depth. As sea-water weighs about 64·18lb. per cube foot, the pressure on a square foot at the depth of 100ft. is about 6,418lb. —J. S. C.

[52995.]—**Pressure of Water.**—The pressure at the bottom is in proportion to the depth. The general rule is to multiply the area in feet, by the depth in feet, and the result by 62¼ (the weight in pounds of a cubic foot in water), the result being the pressure in pounds, e.g., the pressure of 1 square foot at a depth of 1 mile:—1 × 5280 × 62¼ = 328,660lb., or about 146 tons. In the supposed case of a bladder, the pressure would be exerted equally over all the area of it in the above proportion, that is, 146 tons per foot supl.: or say, one ton per inch supl. at the above depth, which would compress the air contained in the bladder into about $\frac{1}{130}$th of its bulk at the surface. Material of bladder and temperature are disregarded.—Ditton.

[53000.]—**Slide-Valve Motion.**—It is Joy's valve gear, illustrated on p. 411, last volume. I suppose you know there is a royalty to pay. See p. 224, ante.—Essar.

[53002.] — **Strength of Beam.** — The usual practice is to consider that a uniformly distributed load may be twice the safe load in the centre, and as the strength varies in proportion to the length, the beam at 12ft. space would carry the same load (4 tons) uniformly distributed, as the beam at 6ft. would carry at the centre.—Ditton.

[53002.]—**Strength of Beam.**—If a beam can carry 4 tons in centre of 6ft. span, a beam of same section can carry 2 tons in centre of, or four tons distributed on, 12ft. span. The weight is inversely as the span, or weight × span in any case = weight × span in any other case, the section remaining the same. But when the span is large in proportion to the depth of beam, the stiffness as well as the strength must be considered.—J. S. C.

[53002.]—**Strength of Beam.**—Ought not "E. E. R." to have given the weight of the beam itself? If the beams are of equal and similar section, the equal distribution of the load would exactly compensate for the doubling of the length. But the weight of the beam itself is now doubled, and so the load will have to be lessened in proportion to that weight. The longer beam will have twice the resilience of the shorter one, but that may be quite useless, for "E. E. R.'s" load may not bring resilience into play. As the safe load is some fraction of the breaking weight, I do not see how increase of span can affect it, except, of course, in the same way it affects the breaking weight at the same time. I should like to hear what some of our practical friends say about it.—C. N., Egstow.

[53002.]—**Strength of Beam.**—For similar supports and conditions of loading, the strength of a beam varies directly as the breadth and square of the depth, and inversely as the length; the formula being—

$$S = \frac{k\,b\,d^2}{l}$$

where k is a constant, depending upon the nature of the beam, and upon the units employed. As regards the position of load and supports, we have—

	Strength.
Supported at one end, loaded at the other ..	1
,, ,, load distributed	2
,, at both ends, loaded at centre ..	4
,, ,, ,, load distributed ..	8

Assuming that the beam in question is supported at both ends, it would, when doubled in span, take only half the load at centre; but it will bear the same load if distributed.—Wm. John Grey, Elswick Science School.

[53003.]—**Soda and Alum.**—The change on mixing solutions of caustic soda and alum consists in the precipitation of aluminium hydrate, and is expressed by the following equation:—$Al_2K_2(SO_4)_4 + 6NaHO = Al_2H_6O_6 + 3Na_2SO_4 + K_2SO_4$.—Wm. John Grey, Elswick Science School.

[53003.]—**Soda and Alum.**—If a solution of sodic oxide (Na_2O) be added to a solution of alum ($S_4O.Amo_2Al_2O^6$), a precipitate is formed, viz.:—Aluminic hydrate (Al_2HO_6). This precip. is soluble in an excess of sodic hydrate (NaHO), but may be reprecipitated by ammonic hydrate (ordinary liquid ammonia) AmHO.—C. N., Egstow.

[53003.]—**Soda and Alum.**—If "Querist" means washing soda by "soda," which contains hydrate as well as carbonate, the ppt. would be aluminic hydroxide ($Al_2(OH)_6$) or hydrate. The reaction would be: Sodium hydrate and aluminium and potassium sulphate, forms sodium sulphate and aluminium and potassium hydrates.—R. A. R. Bennett.

[53005.]—**California.**—If "J. M. M." will send to Mr. Kingsbury, 41, Finsbury Pavement, E.C., he can obtain a list of instructive works on California, which will probably help him. Your correspondent must, however, remember that the skill which is paid for here is not in such demand there, for excellent fruits grow wild. Florida seems to be best for oranges, but California is in the first rank for the vine, and raisin raising is a rising and remunerative industry. The one thing needful is capital to start with; then the emigrant should do well.—N. E. Child.

[53007.]—**Electric Gas Lighter.**—This query was actually answered so recently as p. 436, reply 52660. As stated, it is understood to be the chloride of silver cell, and directions for making have been given several times. See p. 224, this volume.—Nun. Dor.

[53009.]—**Magneto-Electric Machine.**—See that the slits between commutator are free from metallic particles, also test for insulation. Your magnets want remagnetising.—W. H. E., Coventry.

[53009.]—**Magneto-Electric Machine.**—Cannot say for certain what is wrong with your machine without seeing it: but, probably, one or both of the commutator springs, or the contact-breaker spring, has got bent so that it does not rub on commutator, &c.—F. R. Street, Hitchin.

[53009.]—**Magneto-Electric Machine.**—1st. The magnet may now be too weak. Such a magnet ought to pull 10lb. 2nd. The fine wire round the armature may be broken at some point. Test this by sending a current from a battery through the wire into a galvanometer. 3rd. The silk covering may be damp, and the insulation imperfect. Dry it by leaving it over the mantelpiece for several days, and try again. 4th. The springs (brushes) which take off the current do not press properly on the split ring. 5th. The brushes press continuously, and are not furnished with interruptor: hence current, but no shock.—S. Bottone.

[53015.]—**Expansion.**—(1) The rate of expansion of gases, which is uniform for all degrees of heat, is $\frac{1}{273}$ of the volume of the gas at 0° C. for each degree increase of temperature. Thus, 273 cubic inches of a gas at 0° C. would measure 274 cubic inches at 1°, 275 cubic inches at 2°, &c. The expansion for each degree of the Fahr. scale is $\frac{1}{490}$ of the original volume at 32° F. The law relating to pressure is that "the volume of a gas is inversely as the pressure." Thus, 100 cubic inches of a gas under a pressure of 30in. would expand to 200 cubic inches were the pressure reduced to one-half, and shrink, on the contrary, to 50 cubic inches if the original pressure were doubled. The standard pressure at which gases are measured is 760mm., or 31in. of the barometer. (2) Liquids vary exceedingly with regard to expansion. They expand more rapidly at a high than at a low temperature. (3) Sulphuric acid of sp. gr. 1·85, between 0° C. and 100° C., apparently expands about $\frac{1}{17}$.—Student.

[53016.]—**Battery for Electric Light.**—Your 40 cells will give you an E.M.F. of 76·0 volts, and a current of about 3½ ampères. If you join your cells up for quantity, you will get 38 volts and 7 ampères, which I think would do for ¼in. carbons, and give you a light of 90 c.p. to a 100. You will find that to manipulate so many cells will be a great deal of trouble and time, as it is advisable to reamalgamate your zincs for every 30 hours of working. If you really mean to go to so much expense and trouble, why not use aqua regia? you will find it cheaper, and give the same E.M.F. Put in the outer jars 10 parts of water, and 1 part of HCl (hydric chloride), and in the porous 1 part of nitric and 3HCl (aqua regia). You ought to get N_2O_5, 14·50 s.p., 4½d. per lb. and HCl 1d. per lb. This solution will not smell so much when working as the ordinary Bunsen form.—G. D. Goold.

[53019.]—**Fixing Windows.**—If A. Lloyd inquires of R. Adams, engineer, Great Dover-street, Boro', he will find, I think, just what he requires, in a reversible sash.—Ditton.

[53020.] — **Who Discovered the Lunar Clefts?**—Many thanks to "F.R.A.S." for replying to my query *re* Crescent Moon; also to Mr. Gwyn Elger, whose beautiful drawings of the lunar surface enrich the astronomical section of the English Mechanic. Apropos of who first discovered the clefts, I venture to note that in Hevelius' lunar map (published half a century before Cassini's) there are drawn three parallel rills. They are to the west of what he calls Mons Climax, and run northwards into the Mare Syrticum. They are designated Fluvius Nilus. I am puzzled to identify these objects in either Webb's or Beer and Mädler's smaller chart. They must, however, represent valleys or clefts which "old Hevel" actually saw, and if the latter, then the date of the discovery of the lunar rills is carried back to within fifty years of the invention of the telescope.—Arthur Mee.

[53022.]—**Black Colour for Cement.**—If A. W. Donald lays his first bed with blacksmiths' ashes and cement, and then finishes with cement and blacksmiths' dust mixed, two of dust and one of cement, he will get a black floor, and one which will polish. I should advise him to have the first bed 1in. thick, and the finishing layer ¼in. thick. He could get the ashes and dust from any blacksmith's shop.—H. E. T.

[53024.]—**Wimshurst Influence Machine.**—The best cement for fixing the sectors to the glass plates is "Kay's Coaguline Cement," to be obtained of almost any chemist. A 6d. bottle will contain more than enough for the job. Carefully

.]—**Patent.**—In a certain process the end in hitherto been obtained by means of rollers or or revolving arms, all of an unyielding nature, e same means, mounted on spring or other flexi- ings. I propose to substitute brushes for this , and want to know whether I can entirely pro- ir use in this direction, that is in all possible : combinations, to prevent others using brushes purpose in any form, or can I only patent their ich a manner as may at the moment occur to me eadiest way of doing so?—H. J. J.

.]—**Eau de Dr. Pierre.**—Can any one give formula of this preparation? It is one of the ds for the mouth and teeth I have met with; but French manufacture, and subject to duty, the England is very high. I should, therefore, like something similar myself, if any reader could e?—Ariel.

.]—**Light for Dark Room.**—I am fitting up oom for dry-plate work, and would like to know e light would be safe to work by. Would some eader say if the following would do? Window ast, 1ft. square; outside is thick plate glass; next ss; then white glass covered with yellow paper d. Or, should I have two pieces of ruby glass?

.]—**Chemical Analysis.**—Will some reader give the details of process for the separation of of the following acids in an organic salt—Formic, xalic, tartaric, and salicylic acids, as required by nce and Art Department in the elementary stage ical organic chemistry?—Young Student.

.]—**Legal.**—To Mr. Wetherfield.—A., a an in Scotland, wishes to marry B., an English- resident in London. As the marriage laws in countries are very different, please say the best cal and expeditious course for A. to pursue. The e to take place in London.—A. Wilson.

.]—**Varnish.**—Can any of "ours" inform me al varnish that will not dry is to be treated? I king terebine with it, and find this answers toler- l; but I should like to know whether sugar of itharge would be better? Also, is it necessary e varnish should be heated when any of these ces are added?—C. E. L.

.]—**Collodion Emulsion.**—On p. 517, Vol. ., Capt. Abney speaks of collodion emulsion as itable for landscape work. Will some one kindly tructions for making the emulsion, and state it will keep after the plates have been plated?—

.]—**Surveyor.**—Will some one give me the ployed by contractors and others by which they a few minutes (upon dimensions being given he estimated cost of a house, barn, or other ?—Gerald Harley.

.]—**Bunsen or Grove?**—In one book I have E.M.F. of Grove's cell is given as being 2·0 volts, Bunsens as 1·80 volts; whereas in Ganot's s" the Bunsen is given as 1·87, and the Grove 1·82. I should be obliged if any of "ours" will which is correct, and which is the best battery wo for ordinary purposes?—L. W. Willis.

.]—**Dynamo Machine.**—Will Mr. Lancaster, ," or some other valued correspondent, kindly e by saying what results I ought reasonably ex- m such a machine I have completed on H prin- follows? Armature 6in. by 2in., 1lb. No. 18, ·55 .M.'s 5lb. each No. 14, ·72 ohm. I get a current; not think it satisfactory. I drive it from lathe; uncertain as to whether I get enough speed or I was unable to get so much wire on the arma- I expected, so as to get resistance higher; but is will not materially affect the result. What he conditions of the external circuit to be to est results?—A. W. Lambert.

.]—**Pressure of Blast.**—Could an ordinary last be utilised for a Bessemer steel converter on scale, say half-ton to a ton of metal? If so, how he tuyeres be arranged?—Ariel.

.]—**Sprained Wrist.**—Some four or five years rained my left wrist, and since then it has always newhat weak, and generally after a few days' , in the way of cycling or boating, will show itself ppearance of a large bump, and will not disap- in unless I allow it considerable rest. Will some ly advise me how to get rid of it altogether, if ? as it is a source of great discomfort and annoy- me—more especially as I wish to go in for gym- this spring.—Mosaic.

.]—**Analysis of Stone, &c.**—Can any of give me the name of a book treating on the ana- rocks, stones, &c., particularly limestones—quali- nd quantitative?—Spark.

.]—**Lapidary Machine.**—Will some Scotch reader furnish me with a plan of the above for and polishing stones and shells, &c.? I believe be bought about Aberdeen, with small engine, ething like £2 a piece. Also description how to e.—Spark.

.]—**Organ Stop.**—I beg to ask advice on the g:—The Stopped Diapason treble of my chamber which consists of wood (compass tenor F to C, 3½ , has a very dull and husky sort of tone. I have inking of removing this and replacing it with a Gedackt of metal. Now the stop at present adds dy to the tone when the remaining stops (metal) n; and what I want to know is—Will I get the dy from the Lieblich Gedackt? Also, has the metal employed as much to do with the tone of pipes as it has with open pipes?—Cymro.

.]—**Concerning Locomotives.**—To "His- "—Will "Historian" kindly give the stroke of ress with 6ft. 6in. drivers which can exert full force at 60 miles per hour (letter 22326, p. 499), does diameter of driver alone affect the speed at ull tractive force can be exerted, or does not f stroke affect it also?—J. L. C.

[53066.]—**Softening Malleable Castings.**—Will any one tell me how to soften a few light malleable castings, at the smallest possible cost, on the best principle out?—E. Willoughby.

[53067.]—**To Mr. Allen, Mr. Grey, and Others.**—Will any of these gentlemen kindly tell me where I can get any information as to the analysis of soda waste? Also any description of the processes in use for the utilisation or the recovery of sulphur therefrom.—H. C.

[53068.]—**Indicator Diagram.**—Will some correspondent kindly answer following? Explain a method of combining the indicator diagrams in a compound engine with cranks at 0° and 180° apart, but without an intermediate reservoir, so as to obtain a single expansion diagram. Having done this, how is the diagram of turning pressure on the crank shaft set out?—C. N., Egstow.

[53069.]—**Estimation of Chlorides.**—Will Mr. Allen, or other of our chemical readers, explain how chlorides can be quantitatively estimated by means of mercuric nitrate? Also the quantity to be taken to make a normal solution? I tried to dissolve the mercuric nitrate in water, and found it only very slightly soluble.—Hydrargyrum.

[53070.]—**Iron Cement.**—Would any of your readers kindly furnish me with a recipe for making a good cement that would firmly secure an iron screw when screwed into iron?—something that could be easily applied when melted, and after being left a day or two to dry, prevents its being unscrewed, except by special force.—Inquirer.

[53071.]—**Empties.**—Perhaps some of your legal correspondents will be good enough to enlighten me on the following:—I live on a line of railway, and frequently have to send empties to London. They are delivered by me at the nearest station, and receipt obtained for them; but the railway company fail to deliver. Can I sue them through the station-master who receives the goods in the country, or must I do so in London? In the latter case, it would be preferable to lose the goods.—Cairo.

[53072.]—**Mill Gearing.**—The gearing at our mill is driven with ropes off the main driving pulley on the crankshaft. Can any of our readers tell me why some of the ropes in working wear on all the surface?—that is, they twist round in working, and the others do not: they only wear on two sides. I should be very glad if any one would tell me how to stop them that wear on all the surface in twisting round, and make them wear on two sides only—that is, where they grip the pulley in working.—J. S.

[53073.]—**Upright Frame Saw.**—Will any reader say which is the best plan to erect upright frame saw to be used for cutting deals into boards? The building is constructed of wood. The saws to be driven from overhead. Diagram would be acceptable.—Pine Deal.

[53074.]—**Painting Terracotta.**—Wanted composition of the medium known as "Veloutine," used in terracotta painting. Also medium for painting in oils on silk or satin.—Terracotta.

USEFUL AND SCIENTIFIC NOTES.

The New Skrivanoff Cell.—The following description of this cell is being circulated; but it will be seen that it is simply a chloride of silver cell, with caustic potash instead of chloride of zinc. Two of the cells, contained in ebonite cases buckled to the belt of the performer, keep a star light going, and the light is readily controlled by the wearer. Each cell consists of a zinc plate bent into the form of a U, and holding in its inside a plate of silver coated with chloride of silver. The zinc plate forms one pole of the cell and the silver the other. A solution of caustic potash—75 parts potash to 100 water—is poured in, and as a porous diaphragm, the chloride of silver is covered with parchment paper. The vessel is of ebonite, with closed mouth, which, however, is opened when fresh liquid has to be put into the cell. This is necessary after every hour's run, and the chloride of silver has to be replaced after three or four hours' of use. The cell is thus expensive; but this is of minor importance in theatrical work as compared with its small size and weight—100 grammes (3½oz.)

The *American Manufacturer* (Pittsburgh) says:—"Messrs. McIntosh, Hemphill, and Co. are interested in the construction of a tank car for the transportation of natural gas. The car is being built at the Swissvale Car Works. It is an ordinary flat car containing a cylindrical tank of ½in. steel, 10ft. in diameter and 35ft. long. The tank is to be filled at the Tarentum wells, and is capable of containing 20,000 cubic feet. Mr. Hemphill considers the scheme a practical one. At any rate he proposes making the trial."

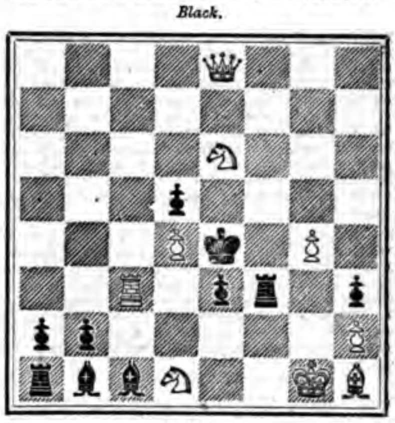
It appears that the Arlberg Tunnel will be finished by the end of May, and the Arlberg Railway by the end of October. The measurements which have been made since the meeting of the two headings of the tunnel show a horizontal divergence of 43 millimetres. A re-levelling from the central part of the tunnel also shows that the datum adopted at the eastern part of the works has an elevation of 164 millimetres above that of the western end. The total length of the tunnel is 5·68 metres less than was estimated before the boring was finished.

CHESS.

All Communications for this department must be addressed to J. Pierce, Bryn Rhedyn, Llandwrog, Carnarvon.

PROBLEM DCCCLXXV.—By G. J. Slater.

Black.



White. [9+10

White to play and force Black to mate him in three moves.

Solution to 873.

White.	*Black.*
1. Q-K B 2	1. Anything
2. P or Kt mates	

(Two variations.)

NOTICES TO CORRESPONDENTS.

Correct Solutions to 872 by R. A. Bennett, Dicky Sam, and F. Kenney; to 873 by R. A. Bennett, E. S. Follwell (this problem, giving Black only one piece capable of moving, circumscribes an otherwise pretty position), W. H. Evans, Dicky Sam, Rev. W. Anderson (Old Romney), F. Kenney, J. G. E (Sittingbourne).

F. Kenney.—Your first solution of 872 will not do; as after 1. $\frac{}{\text{B-Q sq (ch)}}$ 2. $\frac{\text{R-B 7}}{\text{Kt-Kt 5 (ch)}}$.

J. G. E.—We have entered you on new Game Tourney. Two games will have to be played simultaneously, and each player has to play one game with every other. Return move must be sent within two days after move received, except under special circumstances allowed by conductor of Tourney. Entrance fee 5s. to constitute a prize fund. Six more entries are needed before the play can begin. Please send name and address.

Game received with thanks from W. Nash.

We shall be glad to have some original problems in two or three moves from our contributors.

"E. M." Tourney Game between G. H. Mainwaring (*White*) and J. Russell (*Black*):—

(Boden's attack.)

1. P-K 4, P-K 4 / 2. Kt-K B 3, Kt-K B 3 / 3. B-B 4, Kt takes P / 4. Kt-B 3 (*a*), Kt takes Kt / 5. Q P takes Kt, P-K B 3 (*b*) / 6. Castles, Q-K 2 / 7. Kt-Q 4 (*c*), Q-B 4 / 8. Q-K 2, P-Q 4 / 9. B-Kt 3 (*d*), B-K 2 / 10. Kt B 3, B-Kt 5 (*e*) / 11. B-K 3, Q-R 4 (*f*) / 12. Q-Q 2 (*g*), B takes Kt / 13. P takes B, P-B 3 (*h*) / 14. K-R sq, Kt-Q 2 / 15. R-K Kt sq, P-K Kt 4 / 16. P-Q R 3 (*i*), Castles (Q) / 17. B-R 2, P-Q 5 (*k*) / 18. P takes P, Q takes Q / 19. B takes Q, P takes P / 20. P-K B 4, P-K R 3 (*l*) / 21. B-K 6, K-B 2 / 22. P-Kt 4, Kt-B sq / 23. B-B 5, K R-Kt sq / 24. Q R-K sq, R-Kt 2 / 25. R-K 4, R-Q 4 / 26. B-R 3, Kt-Kt 3 (*m*) / 27. K R-K sq, P takes P / 28. B takes P (ch), Kt takes B / 29. R takes Kt, P-Q 6 / 30. P takes P, R takes P / 31. R-Kt 4, R takes R / 32. B takes R, B-Q 3 (*n*) / 33. R-K 6, R takes P / 34. R takes P, P-Kt 4 / 35. P-B 4, R-Q Kt 6 / 36. R-B 7 (ch), K-Kt 3 / 37. R-B 6, B takes Kt P / 38. B-K 6, R-Kt 7 / 39. P-B 5, P-Q R 4 / 40. R takes P, P-R 5 / 41. R-Kt 6, P-R 6 / 42. R-Kt 2, R-Kt 8 (ch) / 43. R-Kt sq, R takes R / 44. K takes R, P-B 4 / 45. B-R 2, P-B 5 (*o*), and wins.

Notes.

(*a*) The attack is risky. P-Q 3 safer. The first player, if carefully opposed, should not recover the gambit pawn.

(*b*) P-Q B 3, probably better.

(*c*) Bad; lost time. Kt-K 4 the proper move, or R-K sq.

(*d*) B-Q 3 worth attention; the only way, it seems, of continuing the attack.

(*e*) Black now assumes the offensive, and retains it.

(*f*) If $\frac{}{\text{Q-Q 3}}$ 12. Q R-Q; and if 12. $\frac{}{\text{P-K 5}}$ 13. Q Kt 5 (ch), &c.

(*g*) Wrong to do this before Black has castled on K side. Of course, he now castles Q side, and has a strong attack. P-K R 3, followed by P-K Kt 4 (if B retire to B 4), would have been better.

(*h*) At this point White's front game already looks like a wreck compared with Black's.

(*i*) In view of what is coming, he should have tried to relieve the congestion by Q-K 2, then B-Q 2 or P-Q B 4; but it is difficult to find a good move here.

(*k*) Curious that Black should invite a change of Qs. Another line of play would be P-K R 3, with the intention of pushing forward K B P.

(*l*) Good.

(*m*) Very well played.

(*n*) The upshot is three P's on Q side become passed, which, of course, means a won game.

(*o*) An interesting finish.

ANSWERS TO CORRESPONDENTS.

. *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

. Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

A NEW VOLUME.

The next number will be the last of Vol. XXXVIII. Readers willing to oblige us by recommending "ours" to new subscribers should do so now, when a new volume is commencing. The index to Vol. XXXVIII. will be published on March 21, and cases and bound volumes will be on sale shortly after. Readers desirous of making up their sets for binding the present volume are recommended to do so at once, as the back numbers soon run out of print.

The following are the initials, &c., of letters to hand up to Wednesday evening, Feb. 20, and unacknowledged elsewhere:—

A. S. [illegible].—J. Joselyne.—St. George Gore.—Charles Hill.—Archibald and Peck.—Rev. F. Carre.—Forster and Williams.—J. B. Spicer.—Major Allen.—T. W. [illegible].—F. Shaw.—Organ Repairer.—W. M.—Engineer. [illegible].—Dunedin.—J. H.—Fish.—Orderic Vital.—Young Violinist.—Father.—Ancienne.—J. P., Stafford.—[illegible].—M. L. K.—A Spinner.—Homo.—F. Hughes.

OILSHEET. (It is generally known as varnish for oilsheets; though as it does contain a small portion of caoutchouc, it may be distinguished as rubber varnish. Take a quarter-pound of indiarubber in small pieces (preferably the light-coloured portions from the inside of lumps of pure rubber), and soften to a pasty consistency in half a pound of oil of turpentine. Put that into 5lb. of boiled oil, and heat steadily over a slow fire until it is completely dissolved. Then add 6lb. of boiled oil and a pound of litharge. Heat until an even liquid is obtained. It is generally applied warm, by brushes or by drawing the fabric over it.)—JOBBER. (You do not state the nature of the articles to be gilt. You will find recipes for gilding solutions on p. 19, Vol. XXXV., and in many other pages in back volumes.)—H. A. P. (Hurst and Blackett published Miss Meteyard's "Life of Wedgwood." We do not remember the other work.)—AUCTIONEER. (Use glair—white of egg beaten up to a froth and strained—or thin glue to which a little vinegar or nitric acid has been added.)—SPERO. (It is animal jelly, obtained from the organic tissues of the bones, tendons, and ligaments, skin, &c. Glue is a coarser kind, just as isinglass is the purest.)—MOONGAZER. (Impossible to say, except earthshine.)—J. GRIFFITHS. (What information is wanted? They are woven.)—AN ENGRAVER. (You will find one on p. 286, Vol. XV., and another—the best—in Vol. XIII. p. 349.)—PHONO STENOGRAPHER. (We send a number containing a good method; but much depends on the kind of steel. 2. No one could give any useful advice without examining the eye, and you would be unwise to do anything except under competent medical direction.)—ARIEL. (It would no doubt be possible, but the wind is very uncertain. Several forms of windmill were illustrated in some of the back volumes.)—WILLIAMS. (Put some neat's-foot oil into a glass bottle with some clean lead shavings, and hang in the sunshine; the longer the better.)—A. N. Z., Blackburn. (The book you want was advertised on p. xi. last week.)—GIANT'S CAUSEWAY. (The lectures are published in book form by G. Bell and Sons, York street, Covent-garden.)—AMATEUR PIANO-TUNER. (You would learn more from the replies given in recent back volumes than from any book. There is a little book published by [illegible], 170, Strand, W.C.)—W. G. S. (We do not know, but expect it is sold by dealers in dyestuffs.)—[illegible]. (We really do not know, and as a matter of fact, we believe it is nearly insoluble in alcohol.)—H. H. (5-24ths of an ounce. It is very simple. "[illegible]-carat gold" means that there are 8 parts of gold to 16 parts of alloy—i.e., generally 12 parts copper, 4 parts silver.)—J. K. O'C. (We cannot afford space for lists of books on any subject. Watt's "Electro-Metallurgy," published by Lockwood and Co., is one of the most useful. 2. It is a mixture of lime-water and almond oil.)—E. [illegible]. (Your friend has been "solemnly" poking fun at you.)—SOLAR TIME. (The sixcentric barometer was described in Vol. XXXII. p. [illegible]. We do not understand how its indications are to be read at that distance, except by means of a telescope or an electrical indicator. 2. The subject was practically exhausted not very long ago; but we certainly could not give "working drawings to scale" and full details. Any point of difficulty is a subject for a query.)—K. G. I. (You will find some processes described in Crookes's manual of "Dyeing and Calico Printing"; also much information in back volumes. Most of the processes are patented or kept secret.)—JAS. A. [illegible]. (On the whole, we agree with our correspondent "F. R. A. S.," but we have no room for a discussion on the subject, which has long ago been [illegible] in these pages. "Perfect systems" of orthography and caligraphy and calculation somehow lose their charm as one grows older.)—C. L. TWEEDALE. (We think you must find out the first for yourself; we can spare no more space. The *Monthly Notices* are published by the Society. Information as to membership &c., of the Liverpool Astronomical Society should be sought from the secretary.)—LAUNDRY PROPRIETOR. (We should sue them in the County Court at once for the amount due.)—E. G. TURNEY. (We cannot insert queries asking about prices of passage, or how readers may obtain assisted passages or situations aboard ship.)—AMATEUR ARTIST. (We know nothing about the society, and should recommend you to keep your money in your pocket.)—W. MARTIN. (What is the "squabble on the patent law"? A patent will be cheaper now, and afford you better protection.)—INVESTOR. (If a building society can get its money out, and the managers keep honest, nothing can pay a small investor better. We cannot recommend particular societies, and all information as to payment for shares by instalments must be sought from their respective secretaries.)—IGNORAMUS. (No: tradesmen are especially appointed as such.)—ATHLETE. (This is not a sporting paper.)—GEO. GENNINGS. (Do you seriously think we can find space to discuss the maunderings of mystics? Some of the statements you quote are perfectly true—i.e., they are accepted by astronomers; but the author's deductions—well, they are about as true as Jack and the Beanstalk; that *may* be true, you know, for all we can *prove to the contrary*; but we don't discuss it seriously.)—R. M. L. J. (You mean the audiphone—a bit of thin wood or cardboard about 8in. by 6in. slightly bent, and held by the teeth.)—L. W. WILLIS. (See p. 330, Vol. XXIX.; an illustration of the quadruplex arrangement on p. 552, Vol. XXI.)—J. F. PINK. (Not suited to the work. See recent replies.)—W. G. (See replies in recent numbers. The best battery free from fumes is one of the bichromate forms. You will have to arrange the cells in series; the lamps you can please yourself about.)—POTENTIAL. (Will not the articles in Vol. XXXVI., and the many notes on the subject in our volumes suit you? All that can be given without practical tests will be found in any textbook of the science.)—RENNES. (See recent back numbers. The query has been answered frequently.)—MECHANIC. (The Whitworth Papers are published by E. and F. N. Spon, Charing cross, W.C., and T. J. Day, Manchester; but they can be had of any bookseller. We think the price is a shilling.)—ONWARD. (You will find answers to your questions in the back volumes; but there is no hand machine to produce such a light as you require. If you are not satisfied with lamps, try the oxyhydrogen light.)—JOHN STARK. (The only address we know is that you mention of the firm who fit the launches. A letter addressed to care of them would no doubt reach him. The only reference we have had was a news par. at the time, and we have not seen any description of the motor.)—AMATEUR. (One recipe on p. 200, last volume. It is made of equal parts lead plaster, beeswax, olive oil, and yellow resin, with enough whiting to make a paste.)—PHYLLIS. (Directions for making on pp. 227, 296, last volume. You do not say how you coupled the cells. Should be zinc of one to carbon of next.)—T. L. (The question has been frequently answered. If the marks are on the polish they can be easily removed by rubbing with a bit of rag and water; if they are through the polish into the wood, it is clear the part must be repolished after removing the stain with oxalic acid.)—YOUNG AMATEUR ELECTRICIAN. (Gower's telephone, p. 244, Vol. XXIX.; the new one p. 510, Vol. XXXII.)—A SCOT. (There are several in back volumes; but they are makeshift devices. See the appliances to be found in the tool lists—such as that issued by Churchill and Co., Cross-street, Finsbury.)—A YOUNG ENQUIRER. (They are very old. You will find a good deal about them in back vols., and especially on p. 442, No. 389, or p. 333, No. 376.)—THE EAST NEUK OF FIFE. (See p. 515, last week, and the indices generally. Most cyclopædias contain the required information.)—J. R. JACK. (Make whichever you like; but as the modern ones are little more trouble and vastly better when made, you will do well to follow the directions given in recent volumes.)—THETON. (The physician no doubt understands what he is about. By using spectacles now, it is probable the patient will not require them when he is twenty-one. It is difficult to assign the cause, except that the eyeball is too long from back to front, and without spectacles the "disease," as you call it, would become worse.)—DUX SPERO SPIRO. (What about the patentee? That settled, you will find directions in almost any volume since XXIX. You will find a receiver illustrated in the number for June 29 last.)—C. L. TWEEDALE. (Methods of silvering glass have been given many times. See p. 22, Vol. XXXIV., No. 862, and the index of that volume.)—W. ANDERSON. (It proceeds from the stomach or the teeth. No one can do more than guess without examining you. If there are no hollow teeth, clean with areca-nut charcoal, and if the breath is still offensive, you will know the cause is in the stomach, or in some organ which should not be attacked by medicines except under the advice of an expert. Charcoal biscuits are, however, harmless, and may do good.)—W. BENNETTS. (1. The Cantor lectures on that subject at the Society of Arts, published by G. Bell and Sons, York-street, Covent-garden. 2. We do not know.)—DESERT DOOR. (Not yet. Messrs. Spons, Charing-cross, will tell you when and the price.)—NEMO. (H. Amati lived about 1600, but his son Anthony, and grandson Nicholas were also distinguished makers at Cremona.)—[illegible]. (The first two questions frequently answered. The third is answered by referring to the nature of the paper, which is easier separated in the plane of the fibres than across.)—[illegible]. (The question has been answered at length recently. See pp. 117, 120, 142, 331, Vol. XXXVI., and the index to last volume. Part of the question should be put to those who deal in such things.)—CAIRO. (Something like "Gerter.")—CHRIS. (Try frequent washing, with a little borax in the water; daily brushing, and leave nature to do the rest. There is no cure.)—J. H. WARD. (The illustration and description on p. 5[illegible]1 should be sufficient to give you an idea, but if you refer to p. [illegible], Vol. XXXVII., you will find "Signal" writing. "For such a purpose nothing is required but a clock having a wheel turning once a minute, with a point on it touching a spring to close the circuit. The local clocks may be merely a train driving the hands, with an electro-magnet and catch to move the first wheel [illegible] a minute, or oftener if desired.")—A SUFFERER. ([illegible] consult a medical man.)—A TEN YEARS' [illegible]. (Full and explicit directions for making a [illegible] were given in Vol. XXVII. p. 157—not six [illegible].)—H. KING. (It depends on the motor; but [illegible] twice as many as would be needed with bichromate.)—G. FRYER. (Must be due to something in the [illegible] or to the presence of wax. Try the effect of [illegible]. 2. You can silver it by rubbing on the paste [illegible] chloride of silver and cream of tartar, or you could [illegible] it plated cheaply by the bath process.)—[illegible]. ([illegible] mean its commercial preparation, and the [illegible] would be better put to a professional chemist. [illegible] large scale it is prepared by fusing crude [illegible] with double the quantity of powdered native [illegible] phate, washing out the baric chloride rapidly [illegible] water and crystallising.)—W. D. L. (Any [illegible] cotton that will lie close will do. It is not [illegible] anything until made up. 2. With the fine [illegible] and oil. 3. Better see the lists of some of the [illegible]. The sort depends largely on the position [illegible]. 4. By weaving and felting the prepared [illegible].)—THURGOOD. (Two articles, giving complete [illegible] in French polishing, will be found in the [illegible] Oct. 29 and Nov. 12, 1880. Both can be [illegible] publisher for ten halfpenny stamps.)—[illegible] only method of "cold soldering" is that [illegible] p. 81, Vol. XXXV.)—WM. [illegible]. (We [illegible] they are unreliable; we have had similar [illegible] before. Let us know later if you get your [illegible] they shall not advertise again.)—P. G. [illegible] chance was, of course, less than the others. [illegible] something else to do than to work out the [illegible] holders of lottery tickets at fancy bazaars.)—[illegible] (A week's notice.)—J. T. A. (Write the [illegible] the Institution of Civil Engineers, [illegible] College, or the City of London College, [illegible] secretaries.)—C. L. TWEEDALE. (See index [illegible] little consideration for our correspondents' [illegible] space.)—COUNTRY. (No. The child, [illegible] been made "weak and sickly" by [illegible] be the real or supposed evils attendant on [illegible]

Every Workman connected with the Building Trades requiring a situation should advertise in "THE BUILDING NEWS," published every FRIDAY, [illegible] at 31, Tavistock-street, Covent-garden, London, W.C.

"THE BUILDING NEWS" is the Principal [illegible] senting Architects and Builders, and has the largest [illegible] of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. [illegible] more "Lists of Tenders" for new work [illegible] any similar paper, and can thus judge where work [illegible] had. He is also specially invited to make use of [illegible] munication" if he wants to know anything about [illegible] write to the Editor if he has any suggestions to make [illegible] advertise in the paper when he wants work.

The charge for Advertisements for Situations is [illegible] for Twenty-four Words, and Sixpence for every Eight Words.

TERMS OF SUBSCRIPTION

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, post-free to any part of the United Kingdom. For the United States, 3 dols. 25c. gold; to France or Belgium, 13s. [illegible] via Brindisi, 15s. 2d.; to New Zealand, the [illegible] Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. [illegible] numbers cannot be sent out of the United Kingdom by ordinary newspaper post, but must be remitted for at the rate of 6d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 8d. each copy, to cover extra postage.

Vols. XXIV., XXVII., XXVIII., XXX., XXXI., XXXII., XXXIII., XXXIV., XXXV., XXXVI., and XXXVII. in cloth, 7s. each. Post free [illegible].

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in March and September, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, [illegible] each, through any bookseller or newsagent, or [illegible] each post-free from the office, except index numbers, which are 3d. each, post-free 3½d.

Indexes for Vols. I., VI., VII., VIII., and IX., 3d. each, post free 3½d. each. Indexes to Vol. XI. and to subsequent vols., 2d. each, or post free, 2½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a coloured Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue the Subscription.

Epps's Cocoa.—GRATEFUL AND COMFORTING.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—[illegible]—Made simply with boiling water or milk. [illegible]—JAMES EPPS and Co., [illegible] London.—Also makers of Epps's Chocolate Essence.

Holloway's Ointment, aided by the Pills. [illegible] thoroughly purified by these Pills, and [illegible] on the surface are effectually [illegible] without pain or danger.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, FEBRUARY 29, 1884.

HE CENTRAL INSTITUTION OF THE CITY AND GUILDS INSTITUTE.

THE scheme for the organisation of the Central Institution of the City and uilds of London Institute, which has been commended by the Executive Committee the Council for adoption, is a document ssessing much interest for all interested the work of technical education. The ject of the Central Institution is to pro- de for London a college in which advanced struction in those branches of knowledge hich bear upon manufactures and arts will given to students who can afford to pay e fees, or who may be fortunate enough obtain "exhibitions" covering the whole part of their educational expenses. The heme has "South Kensington" written oadly over its face; and it is a matter for gret that the Guilds of London, now that ey are apparently cognisant of the fact t they have long neglected their duties, not keep the whole control of the City Guilds Institute within their own ds. The object of the Central Institution, ording to the "scheme," is to train tech- al teachers, proprietors and managers of mical manufactories and of other in- trial works, as well as mechanical, civil, electrical engineers, architects, builders, persons engaged in art industries; for ch purpose the Institution will consist five chief divisions—viz., 1, Chemical hnology; 2, Engineering—mechanical, l, and electrical; 3, General manu- tures; 4, Architecture and Building Con- ction; 5, Applied Art. But inasmuch the Royal School of Mines is already blished as a training school for mining gineers, no provision will be made for instruction of students in that branch industry; and consequently, geology, eralogy, and metallurgy will not be luded in the list of subjects of truction — for the present at least. first sight it might appear that this Cen- l Institution, which is located in the Ex- ition-road, would cover the field, or a rtion of it, already occupied by the Science d Art Department; but that would be a stake, because the "main purpose of the truction to be given will be to point out application of different branches of ence to various manufacturing industries; d in this respect the teaching will differ m that given in the universities and in her institutions in which science is taught ther for its own sake than with the view its industrial application." The distinc- n is clear and obvious: at the institution se by, students will still continue to be ught science for its own sake; but at the w establishment, science will be taught pressly with reference to its application various branches of our manufacturing dustries, and for this purpose a separate aff of professors, demonstrators, and labo- tory assistants will be required; for, in ldition to lecture theatres and classrooms, e Central Institution will be fitted with boratories, drawing offices, and work- ops; and opportunities will be afforded r the prosecution of original research with e object of the more thorough training of e students, and for the elucidation of the eory of industrial processes. It will be en that the technical education of the working man," who was the object of the ovement primarily, is left entirely out of e scheme, except in so far as he may be cluded under the head of "technical achers." These latter will consist of students entering the Institution from the Finsbury Technical College, or other similar colleges in the provinces, by means of exhibitions; of students selected at the May examinations in technology who pass with special distinction in the Honours grade; and of registered teachers of the Institute, who, during certain months of the year, will receive gratuitous instruction, and have the use of the laboratories, &c. The students proper will consist of persons not under sixteen years of age, who, having passed a matriculation or entrance examination, are prepared to take a complete course of instruction with a view to some professional or industrial occupation. These students will consist of those who pay full fees and of those who enter by means of "exhibitions." The third class of students will consist of those who, already engaged in industrial pursuits, may desire to attend special courses with the view of learning the scientific principles underlying the manufactures or arts with which they are connected. The matriculation examination for students who enter with the view of obtaining a diploma will include mathematics pure and applied, chemistry, physics, drawing, and modern languages; and the fee for the courses will be about £30 per annum, while a fee of about £20 per annum will be charged to those students who wish to take special courses and occupy the greater part of the day in laboratory practice and research work. To encourage the latter, advanced students, and non-matriculated students (under very special circumstances), will be provided with separate laboratories, in which to work free from distraction or disturbance. It is clear from the above that not only is the technical education of the working man quite beneath the scope of the Central Institution, but that the working classes are practically excluded, unless some few of them are fortunate enough to gain exhibitions of sufficient value to provide for their support in London during the two or three years over which the course of instruction will extend. To provide for the teaching of the students it is proposed to elect forthwith four professors — those respectively of chemistry, mechanics and mathematics, engineering, and physics—at salaries of £1,000 per annum each, with a prospect of increase, depending upon the number of students in attendance; leaving the professorships of architecture and building and of applied art vacant until the organisation of the Institute has been established. The salaries of the four professors represent a considerable portion of the funds that will be needed; but to provide the requisite instruction in the department of chemistry it will be necessary to have one chief professor, who will devote the whole of his time to the Institution, and two assistant professors, each taking charge of one of the three large laboratories which have been provided. Besides these professors, demonstrators, laboratory and lecture assistants, and attendants will be required—a remark which applies to all the departments; but in those of engineering and physics the election of an additional professor is contemplated at an early date. Besides what may be termed the professorial staff—the planets and their satellites—there will be a number of lecturers, who may or may not be on the permanent establishment, and who will lecture during the session to the matriculated students, and during the recess to teachers of technical classes in London and the provinces, who will be invited to attend without payment of fee, while it is expected that arrangements will be made by which other persons seeking information on technical matters may be admitted to these lectures. Systematic courses of instruction will be drawn up for matriculated students, which will be obligatory on those desirous of gaining the diploma of the Institute. That will consist primarily of the Associateship, to be granted to students of three years' standing who have passed all the examinations; and secondly, the Fellowship, to be conferred upon those who, having obtained the Associateship and spent at least five years in actual practice, can produce evidence of having done some original and valuable research work, or of having otherwise advanced the industry in which they are engaged. In one paragraph of this "scheme" we are told that should the scheme now proposed be adopted, there are numerous details connected with it which will "need to be carefully worked out"; but it is recommended that the four professors should at once be appointed, because we suppose they are to form the Board of Studies, and it will be necessary to get everything ready before the students arrive, and to select the subordinates of the professorial staff. Any lecturer holding an annual appointment may be elected by sub-committee A a member of this Board; but the organising director and secretary of the Institute, although he may be present and take part in the discussions of the Board, is not to be entitled to a vote, which seems a rather peculiar arrangement seeing that a lecturer may have a vote, especially when it is remembered that this Board will practically have the power of appointing and removing instructors, teachers, demonstrators, and attendants, though nominally "recommending" the Institute. The exact meaning of appointing lecturers to the Board may be understood from the fact that, although at the outset the education of day students is all that will be attempted, it is desirable that evening instruction should be given at the Central Institution, consisting of courses of lectures dealing with some of the applications of science or art to special branches of industry. The Board of Studies will it seems not have the power of selecting and dismissing lecturers, nor even of recommending the Institute to do so; but should a sufficient number be appointed to the Board, they will practically control the vote. The Guilds of the City of London have still the power to control the action of whatever governing body may be appointed to determine the course of procedure in connection with their Central Institution, because they are the chief subscribers of the funds, and by withholding them they can practically throw the casting vote. It is to be hoped that they will give an early indication of their intention to do so, for judging by previous experience, it is easy to foresee that if the scheme as proposed is adopted, the outcome of the agitation for technical education will end in the establishment of a permanent staff of well-paid professors, lecturers, and assistants, whose labours will be devoted to the instruction, not of the workmen of the country, but of those who in London are already well provided for at University and King's Colleges.

THE SPEEDWELL SHOW.

THE annual exhibition of bicycles and tricycles known as the Speedwell Show, was held last week in Bingley Hall, Birmingham, the formal opening being preceded by a speech, in which Mr. Jaffray gave some interesting statistics of the trade. It appears that the average make of bicycles and tricyles now ranges from 500 to 600 per week—the output for last year being estimated at 30,000, while more than 10,000 tricycles were sold last year in the United Kingdom alone. The capital employed is about half a million sterling, and altogether some 10,000 hands are directly engaged in the trade. The exhibition, which contained over 500 machines, is the third held by the Speedwell Bicycle Club, and was extensively patronised by the general public—probably, to a certain extent, because they know that part of the profits made by the Club is distributed amongst the charities of the town. Most of the firms who exhibited at the Stanley Show also put in an appearance at the Speedwell, but there is nothing very novel in the exhibits. Most of the makers who exhibit tricycles dwell on the hill-climbing capabilities of their machines, or on the "speed and power gearing" with which they are fitted; but *the* novelty was the convertible boat tricycle of Captain Terry, in which he journeyed from Paris to London last summer. The boat portion consists of a light metal framework 12ft. long, 3ft. 8in. broad, and 2ft. deep, which is covered with waterproof canvas when it is desired to travel on the water. A steam tricycle is also shown. Ellis and Co., of Fleet-street, exhibited their Facile bicycles, which are rapidly coming into favour amongst those who want a safe machine, but have not room to stable a tricycle. Messrs. Devey and Son, of Wolverhampton, had on view their cheap bicycle known as the Working Man's Friend, the price of which, compared with others, is remarkable; and Mr. T. Clarke, of Manchester, had also some notably cheap bicycles, while Mr. Burdess, of Coventry, staged some of his "Sterling" machines. Mr. Brown had his usual assortment of parts, and also exhibited the new steering gear, in which the wheel is turned by a couple of bands of phosphor bronze winding on a drum. One excellent feature of the Speedwell Show is that the "exhibition" is confined to the body of the hall, the galleries being available for the trial of machines by intending purchasers.

ASTRONOMICAL NOTES FOR MARCH, 1884.

The Sun.

The Method of finding Local Sidereal Time at Mean Noon at any given station will be found on p. 358.

At 5 a.m. on March 20th the Sun is said (technically) to enter Aries, and Spring is supposed to commence. At the instant referred to, he is, in reality, some 6° south-by-east of ω Piscium.

Solar activity continues to manifest itself with but slight diminution, and spots and faculæ of considerable size and beauty appear on the Sun's disc.

The Zodiacal Light may now be seen in the west, above the spot where the Sun has set, presenting the appearance of a luminous blunted cone, with its axis lying roughly in the plane of the Ecliptic.

A Partial Eclipse of the Sun, visible only in high North latitudes, will occur during the early morning of March 27th: but it needs no further mention here.

The Moon

Enters her First Quarter at 1h. 33·1m. in the afternoon of March the 4th, and is Full at [illegible] p.m. on the 11th. She will enter her Last Quarter at [illegible] on the night of the [illegible], and be New at [illegible] a.m. on the 27th. [illegible] high tides may be expected about the [illegible].

Ec Eclipse: Oc Occultation; Tr Transit of Satellite; Sh Transit of Shadow; D Disap R Reappearance: I Ingress; E Egress. The printing of a phenomenon in italic indi its visibility is rendered doubtful, either by the brightness of the twilight or by Jupiter's pr to the horizon.

The Moon will be in conjunction with Saturn at 7h. p.m. on the 3rd; with Jupiter at 1 o'clock in the afternoon of the 7th; with Mars at 5h. a.m. on the 8th; with Mercury at 2h. a.m. on the 27th: with Venus at 6h. a.m. on the 30th; and, for the second time this month, with Saturn at 5h. a.m. on the 31st.

Mercury

Is a Morning Star up to the time of his disappearance, in superior conjunction with the Sun at 8 a.m. on the 30th, but is very poorly placed for the observer during any part of the month. His diameter decreases from 5·6 on March 1st to 5' by the 14th, at which angle it remains stationary.

Day of Month.	Right Ascension.	Declination South.	Souths.

31	0 47·2	4 5·0 N.	0 10·1 p.m.

The path indicated by the above Ephemeris begins in the North Eastern part of Capricornus, and extends through Aquarius into Pisces.

Jupiter

Like Mars, may be seen all night long: b the case of all the planets, is most fav placed when within an hour or two meridian. As the distance of the earth fr increases, obviously his diameter will di As a matter of fact, it decreases from the 1st of March to 37·2" on the last day month. He, however, continues to p noble and all-repaying sight to the obser the telescope.

Day of Month.	Right Ascension.	Declination North.	S
	h. m.	° ′	h.
1	7 48·4	21 44·1	9
6	7 47·3	21 46·9	8
11	7 46·6	21 48·9	8
16	7 46·2	21 50·0	8
21	7 46·1	21 50·1	[illegible]
26	7 46·4	21 49·5	[illegible]
31	7 47·0	21 47·9	[illegible]

To the naked eye, Jupiter will not s move from a point in the confines of G almost due west of the 6-5th mag. Star

Venus

Is an Evening Star during the whole of and is a brilliant and conspicuous objec the western horizon long after sunset. S y fair position for the observer, but the disc xhibits in the telescope, although increasing ameter from 14·2″ on the 1st to 17·2″ by the is still gibbous, and hence does not present ticularly interesting spectacle.

	Right Ascension.		Declination North.		Souths.		
	h.	m.	°	′	h.	m.	
	1	11·2	7	36·5	2	32·0	p.m.
	1	33·1	10	6·2	2	34·2	,,
	1	55·1	12	30·2	2	36·5	,,
	2	17·3	14	47·2	2	38·9	,,
	2	39·6	16	55·7	2	41·6	,,
	3	2·3	18	54·5	2	44·5	,,
	3	25·1	21	2·2	2	47·6	,,

arting thus from a point roughly half-way een ε and μ Piscium, at the apex of a very triangle whereof they form the extremities e base, Venus thus travels across the whole h of Aries, and is found by the end of the h in that blank part of the sky near to (and -west of) the Pleiades.

Mars

isible all night long, and although his lar diameter decreases from 14·4″ on March o 11·2″ on the 31st, he is still an interesting ct in a telescope of sufficient power.

Month.	Right Ascension.		Declination North.		Souths.		
	h.	m.	°	′	h.	m.	
1	8	26·1	23	18·7	9	45·7	p.m.
6	8	23·7	23	15·9	9	23·7	,,
1	8	22·7	23	8·2	9	3·0	,,
6	8	22·9	22	56·1	8	43·6	,,
1	8	24·4	22	40·2	8	25·4	,,
6	8	27·0	22	20·7	8	8·3	,,
1	8	30·6	21	57·8	7	52·2	,,

Hence it will be seen that Mars describes a in the sky to the West, and somewhat to the th of γ Cancri. Up to about the 13th he is velling towards the west, but he then turns nd and pursues a direct path towards the star rred to.

Saturn

s between 1 and 2 a.m. at the beginning of rch, and before half-past 11 at night at the of it. Hence he will be best observed as n after dusk as possible. No perceptible nge in the opening of his ring system will ur, as far as the ordinary observer is concerned, nor will the diminution in his angular meter from 16·4″ to 15·6″ during the month be more noticeable. Our ephemeris of Saturn l be discontinued after this month until his reearance as a Morning Star in September.

Month.	Right Ascension.		Declination North.		Souths.

The Method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in March, will be found on p. 359, and that of determining the Local Instant of its Transit at any other Station, on p. 360.

GERN'S PNEUMATIC ACTION FOR ORGANS.

SOME improvements in connection with the valve action of organs, and also in the methods of obtaining increased pressure of wind, have been recently patented by Mr. Augustus Gern, of Notting-hill, W., the object of which is to simplify the construction and operation of the parts, to avoid loss of wind, and to prevent the objectionable sounds which often result from leakage. In the illustration, Figs. 1, 2, and 3 show an arrangement for working pneumatically the valve of an organ pipe by the combined action of a finger key and a stop slide. Fig. 1 shows the action of the key, Fig. 2 the action of the stop slide, and Fig. 3 their combined action on the valve. In Fig. 1, A is one of the keys, shown as it would be when depressed by the finger of the performer; this movement raising a stud, *a*, fixed (adjustable in height) on the key, and so opening a valve B and closing a valve C. Both these valves are situated in the key duct D, the valve B governing an outlet for escape of air, and the valve C governing a passage from a channel E, which is charged with air at the same pressure as the air in the windchest. When the key A is released, the valve B closes and C opens, so that the key duct D becomes charged with air from E at the windchest pressure. In Fig. 2, F is a slide worked by the stop pull. It has through it a hole G, which, in the position of the slide as shown, forms an escape passage from the stop duct L. When the slide F is pushed in, the hole G is brought to the dotted position G^1, giving passage to the stop duct L from a channel H, which is charged with air at the windchest pressure. In Fig. 3, D is the key duct and L the stop duct, communicating respectively by passages *d* and *l*, with a cavity M containing two connected valves m^1 m^2, either of which is open when the other is closed. N is a piston, connected to, and somewhat larger in area than the valve O which governs the passage to a pipe.

The piston N works freely in a cylinder P, situated in the windchest above and in communication with the cavity M. A spring *n* supports the weight of the piston and valve. When the stop slide is in the position shown in Fig. 2, the stop duct L being then open to the atmosphere, the valve m^2 (Fig. 3) is closed, m^1 remaining open. If now the key A be depressed, as shown in Fig. 1, opening B, and allowing escape of air from the key duct D, then, the pressure in M being relieved, the piston N is pressed down by the excess of pressure in the wind chest, and the pipe valve O is opened. When the key A is released from the pressure of the finger, allowing B to close and C to open, then air from E charges the key duct D and by it the cavity M is charged with wind to the same pressure as that in the windchest. The piston N being thus subjected to as much pressure below it as there is above it, rises, closing the valve O. When the stop slide F (Fig. 2) is moved so as to close the escape from L and to open the passage from H to L, then the pressure in the stop duct L being thus made equal to that in the windchest there is no force tending to close the valve m^2 or to keep it closed. If now, the key A (Fig. 1) be depressed, reducing the pressure in the key duct D, the valve m^1 will close, and as the pressure in M is unaltered, there is no movement of the piston N, and consequently no opening of the pipe valve O. Thus, according as the stop slide F is in the one position or the other, allowing escape from the stop duct L or keeping it charged, the depression of the key A is effective or ineffective in opening the pipe valve O. It is to be understood that there are side by side, a number of ducts D, one for each key of the manual, each of these ducts having a series of passages *d*, one for each range of pipes constituting a stop; also, that for each stop of pipes there is a stop duct L, each of these stop ducts having a series of passages *l*, one to the cavity M for each pipe of the stop. Thus, one key, such as A, governs the valves of all the A pipes of a number of different stops, and one slide F governs the valves of all the pipes in one stop, but no pipe of any stop can be sounded unless that stop is brought into action by putting its slide F in the position shown in Fig. 2, and unless the key A is also depressed. Sometimes, for the purpose of effecting combinations of stops, it is desirable that each pipe valve should be governed by two or more stop slides, and, sometimes, for the purpose of coupling manuals, it is desirable that each pipe valve should be governed by two or more keys. In such cases, the cavity M may have several sets of valves, such as m^1 m^2 arranged in it. Fig. 4 is a section showing the invention for intensifying the wind pressure of an organ or wind instrument of like kind, that is for obtaining a supply of air of greater pressure than that of the air delivered by the bellows. A is a box containing a collapsible vessel B, constructed as a bellows, which, at the bottom, communicates with a channel C provided with a valve *c* opening towards B, and also with a channel D provided with a valve *d* that opens from B. The channel C is supplied with air from the bellows or windchest of the instrument; the channel D is for conducting air at a higher pressure to some part of the instrument where higher pressure is required. The box A has two openings, one to the outer air governed by a valve E, and one to the channel C governed by a valve F. The valves E and F are jointed to opposite ends of a lever G, so that the one is open when the other is closed. On the fulcrum of the lever is pivoted a heavy plate H, which acts as a tumbling weight, and has on its side two studs h^1 h^2 projecting so as to come in the way of the lever G. There is also in H an elongated hole, into which a stud, *b* projects from the middle partition of the bellows B. The top of the bellows B is loaded to the extent required to give the desired increase of pressure, the load however being such as can be raised by the pressure of the air in C. The action of the apparatus is as follows. The valve *d* being closed by the superior pressure in D, and the valve E being open and F closed, air from C passes the valve *c* and inflates B, the air thus displaced in the box A escaping by the open valve E. When the inflation of B is nearly completed, the stud *b* meeting the upper part of the hole in H, moves H until its centre of gravity passes the vertical line through its pivot, whereupon the weight of H causes it to tumble over to the position shown in Fig. 4, and its stud h^1 moves the lever G so as to close the valve E and to open F. The box A being now charged with air having the pressure of the air in C, the bellows B collapses,

Fig. 2

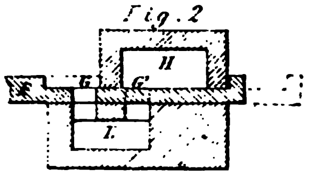

Fig. 4

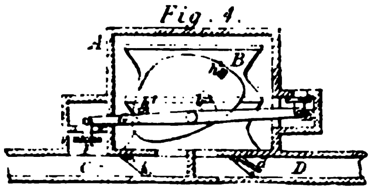

Fig. 1.

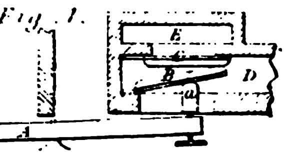

Fig. 3.

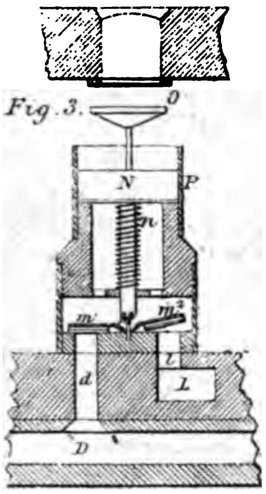


discharging its contents past the valve *d* into D at a pressure greater than that in C by the amount due to the load on B. As the stud *b* approaches the lower extremity of its stroke, it meets the lower part of the hole in H and causes H to tumble over to the right hand, the stud h^2 moving the lever G so as to close F and to open E, whereupon the action is repeated. The channel D may lead to a pressure regulator, and there may be several sets of the apparatus shown in Fig. 4, acting in successive order to deliver wind of intensified pressure into the wind chest or regulator. When still greater increase of wind pressure is required, the channel D conducts the air to a second intensifying apparatus of the kind described, and there may be a series of these, each adding to the pressure of the wind an amount due to the loading of its bellows B.

THE DYNAMO: HOW MADE AND HOW USED.—XIV.*

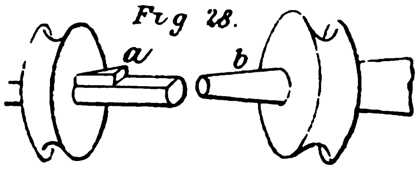
By SELIMO R. BOTTONE.

§ 29. IN order to communicate the motion from the flywheel to the armature, a small pulley wheel, either of iron or brass, is fitted to the back trunnion, just outside the bearing. Such a pulley wheel may be bought at any ironmonger's, and should be about 1¼in. in diameter, and rather over ¼in. thick, with the central hole somewhat smaller than the diameter of the rod which serves for the armature trunnion. This may be attached to the trunnion in either of the two following ways:—1st. By "keying," which consists in filing the trunnion along its length, in one direction only, so as to produce a flattened side; then having, with a rat's tail file, cleaned out the central hole of the pulley to such an extent that the said trunnion will only just enter, to deepen one side (corresponding to the flattened side of the trunnion) so as to admit of a small steel wedge or "key" being inserted (see Fig. 28*a*). 2ndly. By filing the trunnion rod to a slightly conical shape, and producing a similar "coning" in the interior of the pulley hole, which may then be driven on (see Fig. 28*b*, where the "coning" of the trunnion is exaggerated, to render this mode of attachment more plainly visible). Whichever mode of attachment is adopted, one precaution must be taken—viz., that the distance between the back of the field magnets and the pulley should not be *less* than 1¼in.; otherwise, when the limbs of magnets are wound with wire, the flywheel will run too close to them to be altogether safe.

§ 30. The flywheel which gives motion to the armature, should be a pretty heavy wheel, about 13in. in diameter, with a groove in the rim to take the band which drives the pulley, furnished with a wooden handle, for convenience of rotating. Such wheels may be obtained ready made in cast iron, from most ironmongers, as they are sent out with "rotary blowers," "portable forges," &c. Fig. 29*a* gives an idea of the kind of wheel necessary, on a scale of 1¼in. to the foot. The central hole is turned, and only requires fitting with an iron pin, on which it turns. Since the aperture in these wheels is about ¾in. in diameter, the pin must be filed down to half an inch diameter where it has to fit the hole in the flange at the top of the dynamo.

The farthest end should have a rounded head, to prevent the wheel from working off, while the portion which passes into the eye at the top of the flange must have a thread put on it, so as to take a nut (see Fig. 29*b*).

Fig 28.



§ 31. All the portions of the dynamo being now fitted. they should be marked so to insure putting together again in right order after winding. When this has been done, the limbs of the field magnets, at all parts except the channel for the armature, and the inner face of the semicircular top which rests against the wheel bracket, should receive a coat of good Brunswick black, allowing them to dry between each application, in a warm oven. The bracket should likewise receive a coat or two of the same varnish, except where the semicircular tops clinch it. This portion *must* be left metallic, so as to insure magnetic contact; otherwise much magnetic power is lost. Two strips of silk (colour immaterial) 10in. by 3¼in. wide, should now be quickly brushed with Brunswick black, and wrapped, while sticky, one round the one limb, and the round the other limb of the field magnets space between the armature channel bend at the top. (See Fig. 15, where the tions indicated are marked respectively 3¼".) The object of this silk wrapping sulate the wire thoroughly from the iron, prevent any accidental abrasion of the wire, which may take place during winding from short-circuiting to the iron. When the silk has been laid smoothly tightly on, the limbs may be returned oven, and allowed to dry at a gentle heat precisely the same manner, the interior their central portion of the armature (technically known as the "web") must be varnished Brunswick black, and wrapped with one similarly-prepared silk. Three pieces required to do this effectually—viz., two 3⅝in. long by 1¼in. wide, shaped as in Fig. to fit against the inner faces, and one long, by ¾in. wide, to wrap round the Particular care must be taken that every of the inside of the armature's channel tirely covered in silk. When this has satisfactorily performed, another coat wick black may be given (avoiding outside), and the armature allowed thoroughly in a warm oven.

Fig. 29.

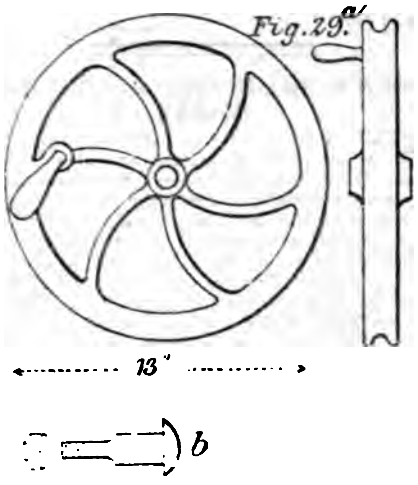


Fig. 30.

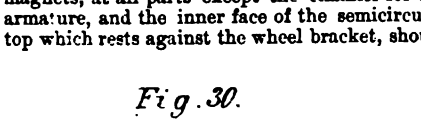

§ 32. Our dynamo is now ready For this purpose we shall require No. 16 single cotton-covered copper field magnets, and about ¼lb. No. 20 covered for the armature. The be careful to get *new* wire, of the ductivity, and very soft; the employ kinky, and hard wire is fatal to success.

MACHINE TOOLS.

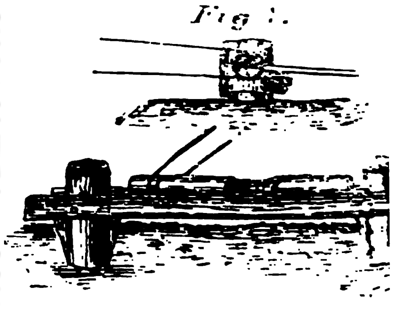
AN ordinary meeting of the Civil and nical Engineers' Society was held inst., the President, Mr. Harkness M.I.C.E., in the chair, when Mr. A.M.I.C.E., read the following paper Tools."

It is quite impossible, in the necessary limits of a paper like this, to give a detailed description of modern is proposed rather to endeavour to early simple types the present cated pieces of automatic mechanism, taking the place of skilled hand labour ally been evolved.

The great principle underlying or automatic tool is the guide principle.

This may be defined in the following Either the cutting tool is mechanically

Fig. 1.



the direction in which it is intended to while the material remains fixed, or the mechanically guided whilst the tool or both the material and the tool are guided in the desired directions at one same time. This latter, it will be seen, is advance. The shaping machine and machine are instances of the first form, the machine of the second, and the self-acting the third, and it is thought we shall find machine, however intricate or automatic, referred to one or more of these forms of principle.

There seems little doubt that the earliest of all machine tools, and what is every machine tool of the present day referred back to and be shown to have gested by the lathe.

It is believed that there is still in use in try districts of India, a form of lathe, than is impossible to suppose anything more The native turner has no fixed carries his lathe and tools about with him.

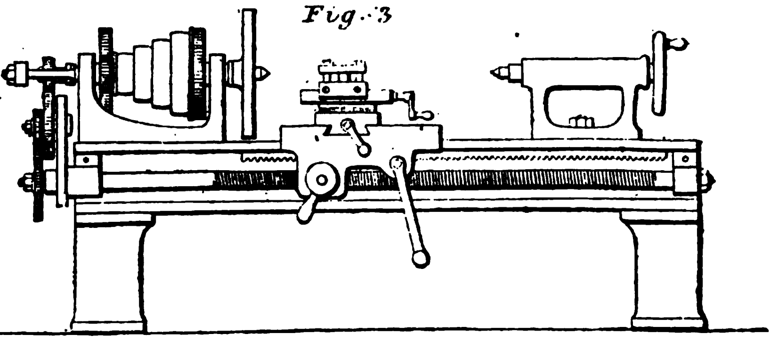
Fig. 3



Having now a true circular motion or guide for the material, the tool, it will be seen, is still at the mercy of the fingers of the workman, and sometimes, if he be clumsy, he finds to his cost that his fingers are at its mercy. Let us now suppose that we rigidly grip the tool in some suitable contrivance, which shall, tool and all, be able to slide along the bed of the lathe, such bed being first made perfectly true and parallel. Then we have not only the material truly and automatically guided in its path of rotary motion, but the tool also guided in a straight line, the result being, truth in the form of the finished material, and what is of equal importance, the capability of reproducing the same form any number of times; both results being independent of any individual skill on the part of the workman.

An obvious advance upon this arrangement is to supply a second sliding guide for the tool at right angles to the first motion or across the bed of the lathe, and we then have the well known slide-rest. The merit of this invention is generally ascribed to Henry Maudslay, and though recent researches have perhaps thrown some doubt upon his being the actual inventor, there can be no doubt that we have to thank him for its introduction.

Fig. 4

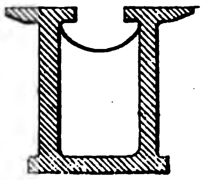


Fig. 5

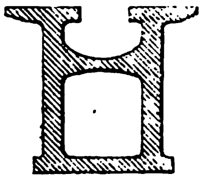
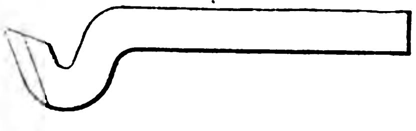


It may probably be asserted that in this combination of the mechanical guidance of the material and of the tool, we have the principle of every machine tool of the present day, no matter how complicated, and that practically they are all derived from the lathe at the stage to which we have now followed it.

The screws which give motion to a tool in a slide-rest were first—as they still are in small lathe—worked by hand; but it was not long before they were automatically connected with the spindle of the lathe, thus giving us the ordinary modern sliding and screw cutting lathe, probably as nearly perfect a tool for its particular purposes as can be devised. Such a lathe is represented in Fig. 3.

Fig. 6

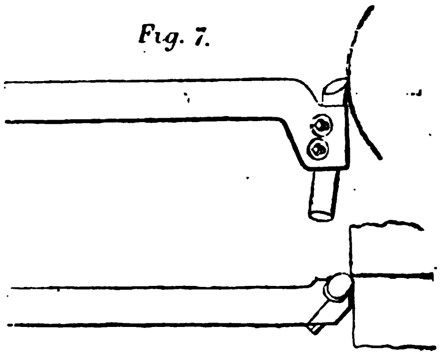


Let us suppose that it is now required to drill a hole. We place our drill in a chuck on the end of the lathe spindle, and either support the object to be drilled against a plate on the movable headstock, or bolt it on the saddle of the slide-rest and feed it up to the drill by one or other of these means. Such a process is satisfactory enough when the work to be drilled is small; but it is clear that the size is limited for want of sufficient height, and and it is, moreover, difficult to adjust in position.

Now, imagine the lathe turned upon end, the headstock being uppermost, with a plain horizontal table to support the work—capable of vertical motion on the bed. No difficulty will then exist in adjusting it in position, and by slightly modifying the form of the framework, it can be adapted to receive work of large size. Here we see the modern vertical drilling and boring machine. When the work is large it will be easier to feed the drill down to the work, than the work up to the drill. For convenience of belting from line shafting the pulley or rigger is taken off the now vertical spindle, and placed on a horizontal one, coupled by bevelled gearing to it. One development of this machine is the radial drilling machine, with the drill-spindle at the end of a radiating arm; not to mention many other varieties of form which have emanated from the simple upright drill. It could perhaps be said that the blacksmith's common upright bench drill is the parent of the modern machine drill, but it may with more justice be traced to the lathe as just suggested.

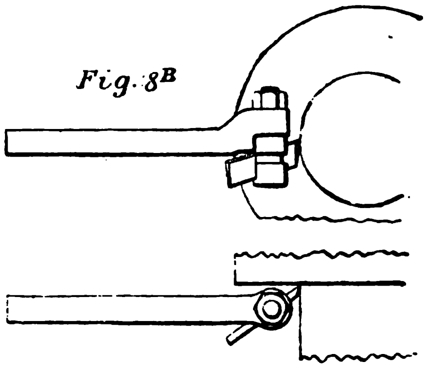
Returning to the slide-rest lathe: We will suppose that we have a small object upon which we want to form a flat surface. We attach it to the face plate, fix a tool in the slide-rest, and feed it across the bed of the lathe; and all being in good order we get a practically level surface; but it is obvious only a small piece of work can be operated on in this manner.

Fig. 7.



We have here the reciprocating motion in one plane of the material to be operated upon, and the feed motion of the tool in a straight line in the same plane, which is all we want for a planing machine. Let us now turn the lathe upon end again, only on the opposite end this time;—stand it on its head, in fact. This position is clearly much more convenient for supporting the work to be planed, as it now lies on a horizontal surface, and let us replace the limited reciprocating stroke given by the rotation of the spindle, by substituting for the lathe headstock a bed, with a carriage or saddle on which to fix the work, capable of sliding to and fro upon it to any required distance. We then have unlimited length of stroke for the work, adjustability for height by means of the bed of the lathe and slide-rest carriage, and feed of the tool by the cross slide; and this, after making a few obvious and convenient alterations in the arrangement of the framing, and supplying suitable driving gear, is the modern planing machine.

Fig. 8B



Now, take this planing machine, fix the tool in the place before occupied by the work, and the work in the place of the tool, so that the tool has the reciprocating motion, and the work the slow cross-feed, and we have another kind of planing machine, commonly called a shaping machine, from its great adaptability, with a few simple modifications, to cut a variety of planes in various relative positions to each other upon the same piece of work, or, in fact, to shape it. Such a tool, by further modification still, will cut slots or other comparatively difficult operations, and is the well-known slotting machine.

The modern milling machine, which is a tool of almost inexhaustible capabilities, in its simplest form is merely the headstock of a lathe with a circular cutter fixed upon the end or nose of the spindle, and the material held in a suitable manner in the slide-rest, and then by feeding the work under the cutter either a groove can be cut or a surface planed; and if a rotary motion be imparted to the material as well as a longitudinal, spiral grooves or cuts are the result. While on the subject of milling machines, it may be mentioned that some are made in a form similar to that of a planing machine, and by their means surfaces of a great length can be milled. One firm, makers of machine tools, uses such a milling machine for the planing or facing of the beds of lathes. The bed of a screwcutting lathe has six distinct surfaces which have to be planed: the two flat tops, the undersides of the two V's, and the two inside edges. The machine has six cutters working simultaneously, and the lathe-bed is only passed once through to complete the operation.

Valuable as a milling-machine is, it was not till a satisfactory method of sharpening the cutters was devised that it came into any extended use. The old plan was to soften the cutter, sharpen the teeth with a file, and reharden; this always distorted the shape, to say nothing of the fact that it was almost impossible to file the teeth true in the first instance, and in consequence perhaps only a third of the teeth were actually doing work; this caused them to become rapidly blunt again, and the operation of softening, filing, and hardening had to be repeated, to the great detriment of the temper of the steel, which, in fact, was soon rendered valueless. By the present system, after a cutter has been properly shaped it is hardened and tempered once for all, and never sees the fire again. After hardening, it is sure to be warped somewhat; it is therefore placed upon a mandrel in a special grinding machine, and each tooth passed in succession under a small emery wheel revolving at high speed; this not only sharpens each tooth, but renders the wheel absolutely true, so that all the cutting edges do an equal share of work, and have each the same clearance angle. As soon as it becomes blunt it is only necessary to regrind the teeth again as before, and this operation can be repeated until the teeth are so worn away as to be no longer of any use. This ingenious little apparatus is the invention of Messrs. Smith and Coventry, of Manchester, and it is not too much to say that it has made all the difference between the milling-machine as a clever toy, and as one of the most valuable tools in an engineer's shop. The milling machine, in its latest developments, has usurped many of the functions of the planing, slotting, and shaping machine, and even of the lathe, more especially for work of a small character. For copying work, such as making any number of pieces of irregular form all absolutely to one pattern, such as parts of gun-locks, it is specially valuable.

Reverting again to the lathe; the old French lathes are very interesting, curious, and ingenious; in fact, the French until recently were far ahead of us in this respect; but of late years their practice in lathe design has not kept pace with the times. Some of their lathes with what are called traversing mandrels for cutting screws, made a hundred years ago or more, are beautiful specimens of workmanship, and there are not a few still in existence perfectly capable of turning out good work. There is, in the Museum of Arts and Manufactures in Paris, an old lathe preserved, which practically anticipates the modern screwcutting lathe, though of course in a comparatively clumsy manner.

Let us now direct attention to the points of difference between English and American lathes. One of the most prominent of these, is the form of the bed; the English being made with two large flat surfaces to receive the wear of the slide-rest carriage, the American only two, and in rare cases four, little half-round beads for the same purpose; and as the greater portion of this wear takes place in one part of the bed only—viz., near the headstock, the bed soon wears hollow in that place. Again, the English carriage is kept down by what are called "gibbs" screwed on it under the V-edges of the bed; the American, even in lathes by their best makers, is usually kept down by weight only. The supposed origin of this form of bed in America is rather curious. The early lathes had wooden beds, which answered well enough till the slide-rest came into use; then upon the top of the bed strips of half-round iron were screwed down and filed into truth; this gave, when new, a fairly satisfactory bed for the carriage with the minimum of surface to be fitted, which, as it had all to be done by hand, was a laborious and tedious operation. The simplest way to keep the carriage down was clearly to weight it, and this primitive form is reproduced in iron in their best lathes to the present day. They are consequently unable to take the heavy cuts customary in England; and, indeed, to judge from the appearance of most of their slide-rest tools, they only look fit for scratching the work. We must not, however, decry the American lathe too much, for we have to thank them for a great part, if not the greater part, of the ingenious machine tools of the present day, the milling machine prominently among the number, and the tools turned out by their best makers are exquisite pieces of finished workmanship, by which mere surface-finish to catch the notice of the ignorant is not meant, but accurate fitting of working parts.

The usual way of making a lathe-bed is quite wrong in principle. A little consideration will show that it is a girder subject to torsional strain, and the ordinary form, shown in Fig. 4, which consists of two I-shaped joists united at intervals by cross-pieces, and not joined at the bottom, as shown in the diagram, is little adapted to resist such strain. The proper form would be of a box section, as shown by Fig. 5, and some are now made in this manner.

While on this subject, it may be said that the designs of the top of the ordinary planing-machine bed is most unsatisfactory. It consists of two V-troughs, in which corresponding V-pieces on the underside of the carriage slide. The surfaces of these V's are usually quite inadequate in extent for the friction they have to endure, consequently the heavy pressure and wedge-action of the V's squeeze out the lubricant, and they soon deteriorate in truth; broad flat surfaces with V-edges for "gibbs" would be far more serviceable and accurate.

No matter how admirably our machine tools may be designed and manufactured, they are perfectly useless unless a certain insignificant-looking part is properly cared for—allusion, of course, being made to the actual tool or cutter. It must be of the best steel, properly hardened and tempered, and its cutting edges accurately formed to the correct angle, *and, above all, sharp*, if good work is to be turned out.

The amount of ignorance and prejudice existing among workmen on the subject of the angles of cutting tools is surprising. The apprentice, after a long course of failure, succeeds in grinding his tool so that it will cut, but *why*, he probably could not tell you. It is no uncommon thing to see a slide-rest tool simply tearing or grubbing off the material by mere main force. Not long since the author saw, in a shop, a latheman take his tool to the grindstone to sharpen, and when he had replaced it in the rest, out of curiosity he examined it; the tool was at work on wrought iron, and was perfectly flat on the top with an obtuse angle. I need not comment on the wretched surface left on the material by such an instrument. Of course it removed something, because it was made of hard steel, and the unfortunate material was only comparatively soft iron, and one of the two had to give way; but how it removed it was quite another question. Fortunately this subject is now beginning to receive its due amount of attention in many machine shops, and it is found that when the tools are formed to the proper angles in the first instance, and are always ground accurately to the same angles, not only is the character of the work greatly improved in truth and finish, but the tools will take a heavier cut, and a coarser feed, with less expenditure of power.

The correct angles for the cutting edges of tools for various materials are now perfectly well known: there is no need to make rule of thumb experiments to discover them. It is, however, quite impossible to grind a tool to a given angle with any approach to accuracy *by hand*.

The tool *must* be rigidly held in a slide-rest, which is capable of adjustment to the required angle by means of a division plate, and be traversed to and fro across the face of the grindstone or emery wheel by such slide-rest, water being supplied by an adjustable tube to the edge of the tool the whole time, to preserve the temper. By grinding the tool at sufficiently frequent intervals, a few passes across the stone are only necessary each time, and by these means the tool is always kept in good condition and its angles accurate.

While on the subject of tools, we may note that the ordinary forged slide-rest tool is rapidly being superseded by small cutters held in adjustable tool-holders. The familiar forged tool (shown in Fig. 6) is of course known to us all. Now this is, in the first place, not an easy form to forge accurately; it takes some time, and the frequent heatings necessary in the process tend to do anything but improve the quality of the steel of which it is composed. Again, it is needless to remind you, that for effective work, the point should be at the same height as the lathe centres. When the tool is sharpened the surface is lowered, and the point is then below the centres; the resource is to block the tool up with a strip of anything at hand, which may be too thin or too thick. If the work in the lathe is of small diameter, it is most important to have the point accurately at the height of the centres: if lower it will tend to dig into the work, and if higher there will be great friction caused by the edge below the point rubbing against the work, and it will be impossible to make a clean and good cut. When, after successive sharpenings the tool is worn down halfway, it is of no further use. It can scarcely be reforged, as the shank would be too short, to say nothing of the further injury to the quality of the steel, and it is probably cast on one side as valueless. When a toolholder with cutters is used, the holder takes the place of the shank of the forge tool, and is made once for all.

The cutters are simply short pieces of steel cut off bars of suitable section, with their ends accurately ground to the right angle. They can be adjusted to the correct height in the holder in a moment by means of a centre gauge placed on the slide-rest; and as soon as they become dull they only require to be slightly ground on their ends, and this grinding can be repeated until the cutters become too short to be held in the holder, when they are thrown aside; but the waste of material in this case is most trivial as compared with the waste of throwing away a forged tool.

The tool-holders made by Messrs. Smith and Coventry, whose milling cutter grinding machine was previously described, are of very excellent design, and diagrams of them will well illustrate the subject. (See Figs. 7 and 8.)

It will be seen that in the holders, which are formed to receive cutters made from round steel, the cutters are only adjustable for height; but in the others, called swivel holders, the cutters can also be set at various angles, which is a valuable feature. Such tool holders and cutters are quite as useful in the planing and shaping machine as in the lathe. The round cutters are chiefly used for roughing off; and the swivel cutters, made of V-section of steel and of various forms of cutting edge, for finishing cuts and for getting out sharp angles and corners. Such cutters, when made of good steel, formed to a correct angle and kept sharp, leave the surface of the work with a high finish, which any subsequent barbaric treatment with emery would only mar.

There is a prevalent idea that cast iron and brass cannot be removed in shavings like wrought iron or steel, but must be scraped off; that is, the cutting angle of the tool must be about 80° or 85°. This is very erroneous. It is not contended that so acute an angle would answer as may be employed upon steel or iron; but cast iron or brass can be removed in shavings with a comparatively acute edged tool—about 65° or 70°, for instance—with less labour and with a better finish to the surface than could be obtained with obtuse angles. When a very obtuse angled tool is used, one of its sides will be a perpendicular to the surface of the work, and it is difficult under such circumstances to avoid "chattering," which is fatal to a good finish or fit.

With regard to drills, there is no question about the immense superiority of twist drills over the ordinary flat drill. The flat drill is not a cutting tool, it is simply a scraper, and removes the material by sheer brute force. The twist drill, on the contrary, has a true cutting angle at its edge. Twist drills are, however, worse than useless unless they are ground mechanically; it is impossible to grind them accurately by hand, and it is better to use a well-made flat drill than a badly-ground twist drill. This will be found to account for the latter not being so popular as they should be. The cutting edges of a twist drill should be absolutely of the same length, and at the same angle to the axis, and the angles of clearance should be perfectly equal. This can only be accomplished in a properly designed mechanical grinder, no hand-grinding can ever effect it, grinding lines and all such aids being little better than useless. A twist drill with its edges properly formed will make a hole through which the drill itself will only just pass, and it will take a heavier feed than the flat drill, and at less expenditure of power.

In conclusion, attention may be drawn to the comparison between the little watchmaker's lathe now before you, and the gigantic lathes represented by some of the photographs on the wall, as affording an instance of the great variation in size of the same tool, the operations performed in each being practically of the same character.

COLOUR IN ELECTRO-GILDING

IT is of the greatest importance to possess a knowledge of the art of regulating the current and general working of hot electro-gilding liquids, so as to make the process useful in producing not only deposits of gold, but those of any desired colour. As a general rule, it will be found best to obtain any excessive colour by additions to the bath, and not by attempting to work it up to this by the current or temperature. Thus, to obtain red or green gold of decided colour it will be necessary to make additions of acetate of copper and nitrate of silver. But if it is not required to perpetually gild in this colour, or at least until all the added metal is worked off, the bath will be spoilt for ordinary gilding. It is, therefore, always wiser, when excessive colour is required, to either make up a separate solution for that particular colour, or to make the main bath up in that manner if the work is always to be carried on.

To make up a bath for red gilding, grind a little of the acetate of copper (crystallised) to powder, dissolve in water, and add to the bath, with stirring, every evening as much as may be required. In a new bath, where there will be no troublesome sediment to disturb, the addition may be made at any time, and the quantity augmented if the colour is not sufficiently deep. It must not be forgotten, however, that gold so coloured is not so fine as a yellow gold. Attention should be given to some of the directions which follow, so that the battery power and temperature may be regulated to assist in the production of deep colour, it being important that too many foreign substances be avoided in a good bath.

To obtain green and white gilding the addition is a solution of the crystallised nitrate of silver. This is added in the same way as the copper. A very little (a few drops) will generally produce green gilding, and a little more white.

To deposit a gold of pink appearance is a more troublesome matter. The surface is first coated yellow, and then thinly red, and over this is produced an exceedingly thin coat of silver in a silvering solution. Such surfaces are very lasting, and should be burnished.

A good cyanide gilding solution should be of sufficient strength to allow of its producing from a pale and poor looking deposit to a deep and nearly red rich gold. For such purposes the solution may even contain as much as 1½ ounce of gold per gallon, but over this it is not advisable to go, for the reason that the paler tints are not readily obtainable. The poorer solutions will produce fairly pleasing tints when the current is strong and the temperature high, but the darker shades are very apt to have a dingy appearance, instead of that mellow and clear surface which is the chief aim of the practiced gilder.

A dead gilding will be produced by the addition of a little of the fulminate of gold in solution to the bath immediately before gilding, or dip the articles (brass and copper) before gilding in a mixture of sulphuric and nitric acids.—*Watchmaker.*

PHOTOGRAPHY BY THE MAGNESIUM LIGHT.*

SOME experiments have been recently published on the use of bottles of oxygen in which to burn fragments of magnesium riband, to take portraits by the magnesium light. An objection is the the trouble and cost of making the oxygen, and that means have to be adopted to diffuse the light near its source. The objection to burning the riband in air is that the exposure is longer, and the burnt ash has a tendency to drop off and put out the light before the selected length of metal is consumed.

Some years ago I had occasion to use the magnesium light by night, and overcame the difficulties by the adoption of one part of the principle of Larkin's magnesium lamp. The method may be thus explained. On the top of a firm and solid table is placed a base-board supporting a wooden upright some seven or eight feet long, consequently reaching nearly to the ceiling of the room. At the top is a kind of little brass funnel with no neck, and a large opening where the neck should be. This brass inverted cone was no larger than an egg-cup, and its lower opening was about as large as a fourpenny piece. A tin spirit lamp, with a horizontal neck and flame, is placed below, so that anything falling through the funnel must pass through the flame, yet just miss touching the wick. The combustible substance was magnesium powder mixed with sand. One thimbleful of the powder, for instance, is mixed with two of sand with a spoon or bit of wood on a sheet of paper; then, the sitter being in position and all being ready, the mixture is poured all at once into the funnel. A long sheet of flame of one or two seconds' duration is the result. If the picture prove over-exposed the proportion of sand has to be increased in the next trial, or that of the magnesium powder correspondingly diminished. When once the right proportions are known, portrait after portrait can be produced, properly exposed with dead certainty. No cap is necessary to the lens, provided a candle only is used for the normal illumination of the room, and it is not placed so that an image of it can be thrown by the lens into the camera. The proportion of magnesium powder regulates the proper exposure. At first there was a difficulty, and one only, with this simple apparatus, and that was that the aqueous vapour from the flame condensed on the lower parts of the brass cone, and the powder stuck to the neck of the wet funnel, sometimes blocking it and arresting the flow of illuminating material altogether. The neck of the funnel was therefore cut off, and the lower opening of the cone made rather large. It would be an improvement to use something on which aqueous vapour has less tendency to condense than upon cold brass. The brass, however, was subsequently kept hot by fixing the spirit lamp nearer to it than in the first experiments.

The larger the proportion of magnesium in relation to the sand the longer the flame and the shorter its duration. With a very rich proportion I once had a flame seven or eight feet long, reaching the base-board and burning its surface. The long flames give the necessary diffusion of light, and a white sheet on the opposite side of the sitter improves the shadows. The finest artistic effects of light and shade on the countenance of the sitter can be obtained by this method when the lamp is placed in the proper position.

The sitter need not be fatigued with focussing operations. A candle placed where his face will come will do to focus upon. In fact, it is a capital method for the comfort of the sitter, who must not look in the direction of the coming flame, lest his eyes be dazzled by its magnificent flash, which, however, lasts but a second or two.

SCIENTIFIC SOCIETIES.

ROYAL METEOROLOGICAL SOCIETY.

THE usual monthy meeting of this society was held on Wednesday evening, the 20th inst. The following papers were read:—

(1) "The Great Storm of January 26th, 1884," by William Marriott, F.R.Met.Soc. This storm was remarkable for its violence and large area, as well as for the unprecedentedly low barometer reading at its centre. The author has prepared isobaric charts for each hour from noon on the 26th to 3 a.m. on the 27th, and by this means has tracked the storm across the British Isles. The centre of the depression appears to have first reached the north-west coast of Ireland at noon, and passed in a north-eastly direction over the north of Ireland and across the middle of Scotland, reaching Aberdeen about midnight. Its rate of progress was therefore about 30 miles an hour. A violent gale was experienced all over the British Isles, the greatest hourly velocity of the wind being 68 miles at Valencia at 11 a.m., 70 miles at Holyhead at 2 p.m., 63 miles at Falmouth at 3 p.m., 69 miles at Armagh, and 59 miles at Aberdeen at 5 p.m., 58 miles at Greenwich from 5 to 7 p.m., and 76 miles at Alnwick at midnight. Thunderstorms occurred on the south-eastern side of the depression, and travelled across the south of Ireland and England at the rate of about 30 miles an hour. The lowest readings of the barometer (reduced to sea-level) yet reported were 27·32in. at Kilireggan at 8.30 p.m., and 27·332in. at Ochtertyre, near Crieff, at 9.45 p.m. In the southern part of England directly after the minimum had occurred there was a very sudden rise in the reading of the barometer, in some cases amounting to ·08in. in five minutes. From an examination of previous records it appears that there has never before been so low a barometer reading as 27·32in., so that this storm may be considered as one of the most remarkable that has occurred in the British Islands.

2) "The Height of the Neutral Plane of Pressure and Depth of Monsoon Currents in India," by Prof. E. D. Archibald, M.A., F.R.Met.Soc.

(3) "The Sunrises and Sunsets of November and December, 1883, and January, 1884," by Hon. F. A. Rolls Russell, M.A., F.R.Met.Soc. The author gives a very interesting account of all the special features of the remarkable sunrises and sunsets which have been observed from November 8th to February 2nd. The following are stated to be the marks distinguishing the peculiar sky haze from cirrus:—1. It is commonly much more evenly spread over the sky than cirrus. 2. It is visible (except when very dense or in the neignbourhood of the sun) only about the time of sunrise and sunset. During the day not the faintest trace obscures the clear azure, whereas cirrus becomes more distinct with more daylight. 3. When actually glowing with bright colour its loses its wavy appearance. 4. It has no perceptible motion, unless perhaps when watched through a long period. 5. It does not interfere with the clear definition of the moon or brilliancy of the stars. 6. It lies almost without exception in long streaks, stretching from between south-south-west and west-south-west to between north-north-east and east-north-east. 7. Its radiant point lies not on the horizon, but far below it. 8. If both cirrus and sky-haze be present, the sky-haze begins to shine with a red light soon after the cirrus has ceased to glow above the western horizon. When cirrus is present, however, there is in general a reaction of effects. 9. The sky-haze is destitute of the fibrous twists and angular branches of cirrus, and since the sunlight leaves it in regular progression, it must be stratified at the same uniform level. 10. It has always been visible on every clear day for more than two months, and has been quite independent of wind and weather.

LIVERPOOL ASTRONOMICAL SOCIETY.

THE fifth meeting of the session took place on Monday, 18th inst., the Rev. T. E. Espin, B.A., in the chair.

Mr. Isaac Roberts, F.R.A.S., gave a description of his recent experience in photographing stars and nebulæ. His own investigations had, he said, been undertaken more with a view of testing lenses and apparatus, than with the hope of immediate success. The method he had adopted was to fix two, and sometimes three, cameras on the declination axis of his large telescope, and to take simultaneous photographs of a star-group or nebula, using similar plates, and allowing the same exposure to each. This method had also the advantage of enabling comparisons to be made of the qualities of dry plates for quick photography. He had not found the large lenses necessarily the best, and this was illustrated by a photograph of a considerable number of faint stars, including some of the shading of the great Nebula in Orion, which was taken by one of Ross's ⅜in. rectilinear lenses, whereas some of the photos taken by much larger lenses were wanting in definition.

The Chairman said the results obtained by Mr. Roberts were most valuable. The observatory at West Kirby had lately been furnished with one of Grubb's magnificent stellar cameras, with equatorial mounting and clock motion. It was now in working order, and he hoped shortly to give a satisfactory account of its performaece.

A paper by Capt. W. Noble, F.R.A.S., was read in reply to Mr. Peal's "New Theory of Lunar Formation," (published on page 490 of the ENGLISH MECHANIC). He was curious to learn how the "large volumes of water could emerge and flood the ice-crust, level it, and being repeated gradually raise the level" without leaving the sublunarian space, previously occupied by the water, void. Had Mr. Peal attempted, even roughly, to estimate the stupendous strain upon the lunar framework under such conditions? He could not, either, regard his reference to the fall of meteoric dust in our Polar regions, as in any legitimate sense explaining the very diversified tints which appear on the moon's surface. Everyone who has looked at the moon through a telescope, must be familiar with the light-green hue of the Mare Serenitatis, and the somewhat bluer green of the M. Humorum. Other districts also exhibited a variety of colours, so that the amount of meteoric dust, necessary to produce those effects, would have thrown the recent efforts of Krakatoa wholly into the shade. Moreover, it would be remembered that the photometric determination of the moon's light shows that her surface is nearer black than white. Nor did Mr. Peal seem to consider the recent researches of Lord Rosse, who had calculated that the moon must at times be heated to something like 500° Fahr., a condition that certainly did not obtain on the Himalayas.

Mr. W. H. Davies remarked that Capt. Noble's argument, based on the determination of the moon's light, seemed to have been anticipated by the theory of meteoric dust. But it struck him that this was only getting out of one difficulty into another, since, if the sun's rays were not reflected, they must be absorbed; and then what became of the snow?

Mr. W. H. Gaze, F.R.A.S., read a paper on "The Value of Weights and Means as applied to given Periods of a Variable Star." He had been struck with the importance of having some reliable and universal method of reducing any number of given periods of a variable star, not differing too widely apart, and was led to investigate certain formulæ devised by two members of the society. He came to the conclusion that some weight ought to be given to each observation, and gave a formula for combining the weights and given periods together. He thought, however, that if the weights were not correctly given, a simple arithmetical mean was the best method.

Writing on the subject of the Taurid meteor shower, Mr. H. Corder said it was necessary to refer to this shower, as it seems at first sight to form part of the Taurid system; but, after carefully mapping a large number of radiant points noted by various observers, it seemed to be possible to distinguish certain aggregations of positions. Mr. Denning gives as a mean 44°½ + 22°, but two showers seem so distinct that he would give them as 46° + 27° and 40° + 21°. Besides these, are a number of scattered radiants in Aries and Musca. The Muscids are noteworthy as being very often fine meteors, and this seems to distinguish them from the Taurids, which are rather small.

Mr. A. Stanley Williams said he had examined the head of Comet Pons-Brooks with a power of 110, and there was apparently a central point brighter than the rest. At times nearly the whole of the head was sprinkled with brighter points or condensations, like a star cluster, but none of these were so bright as the central point. The comet bore a power of 150 well, and the brightness of the points was intensified; but the central point, which was not

---

By W. H. HARRISON, in the *British Journal of Photography.*

worthy of the name of a nebula, was not then much brighter than the others.

A simple equatorial mounting for small telescopes, by Mr. W. Harding, was shown and described, and several photographs of stars and nebulae were handed round. Dr. Wm. Huggins, F.R.S., and the Rev. S. J. Perry, F.R.S., Stonyhurst, were elected associates.

SCIENTIFIC NEWS.

In an interesting lecture delivered last week before the Leeds Philosophical and Literary Society, Prof. Ball, the Astronomer Royal for Ireland, spoke of celebrated comets, present and modern, great and small. After describing the appearance and orbits of some of the most remarkable comets, Prof. Ball referred to the shower of shooting stars which was seen in 1866, and mentioned the supposition that these meteorites were the remains of tails of comets.

On Monday last, Mr. G. J. Romanes delivered a lecture on "Instinct" to the members of the Birmingham and Midland Institute, in which, after defining the differences between actions properly called instinctive and those due to reflex muscular or nervous motion, and also those intelligently directed, he dwelt upon the two causes to which instinct is to be attributed, namely lapse of intelligence in actions originating intelligently, becoming by repetition automatical, and natural selection, these two causes acting frequently in combination. He afterwards spoke of the plasticity of instinct, showing, by numerous illustrations, that however perfectly formed the instincts of animals might be, they were capable by change of circumstances of being deflected and even altogether changed. In the case of the dog, for instance, the spirit of fierceness and self-reliance which was characteristic of all wild dogs had been changed by domestication to one of docility and faithfulness, and a sense of dependence upon his master, and in addition new instincts had been developed, such as those of pointing, retrieving, sheep-tending, and guarding property, all of which were strongly inherited. Prof. Romanes referred to some of the difficulties in the theory of evolution, of which at present he admitted inability to furnish a satisfactory explanation.

A series of Gilchrist science lectures is to be delivered on Tuesday evenings, commencing March 4, at the Royal Victoria Coffee Hall, Prof. H. G. Seeley leading the way next Tuesday with a discourse on Ancient English Dragons. On March 11 Mr. W. Lant Carpenter, B.Sc., will discourse on Air, and why we Breathe; followed on March 18 by Mr. P. H. Carpenter, D.Sc., with Fossils, and what they Teach us. On March 25 Mr. E. Clodd will lecture on the Working Man [illegible] Years Ago; April 1, Mr. Ranyard, Sec. R.A.S., on Planets; and April 8, Mr. J. W. Groves on the Dangers and Safeguards of Beauty in Animals.

At the [illegible] annual general meeting of the Hertfordshire Beekeepers' Association, held at Hitchin last week, a satisfactory report and balance-sheet were presented. The thanks of the committee and members were awarded to the Rev. F. G. Jenyns, Rev. J. L. Seager, hon. sec., and Mr. [illegible] P. Sambels for the lectures they had delivered in various parts of the country. The Rev. F. G. Jenyns said that from six hives he had obtained [illegible] of super honey, and, according to the report, Miss Gayton, of Much Hadham, had cleared in 1883 upwards of £[illegible], selling honey in sections at 1s. [illegible] per lb., and extracted at 1s. per lb. This society pays an expert to visit the members and examine their hives.

The output of coal in the United Kingdom is stated to have reached, last year, the high total of [illegible] tons, or an increase of more than [illegible] per cent. on the previous year's total. According to the late Prof. Jevons' estimate, the quantity raised in 1883 should have been [illegible] tons, so that the actual output was [illegible] tons less.

The Commissioners on Technical Education have, it is understood, concluded their labours and will meet again only for formal business. The report will occupy five volumes, and it is stated to be impossible to give a *résumé* of the conclusions which would not be misleading, or at least, not intelligible in the absence of the explanatory details.

A report on the effect of heavy sizing in cotton weaving upon the health of the operatives has been issued. It states that the balance of evidence is in favour of harm resulting not to strong and vigorous constitutions, but to those who are weakly, or have tendencies to rheumatic or pulmonary disease, and recommends that processes by which large quantities of size can be incorporated with the warp without the addition of dust or moisture should be generally applied, and that effective ventilation should be adopted.

Letters from Reikjavik up to the middle of February report a mild winter, with little snow, but rain and heavy southerly storms have been frequent.

News has been received in St. Petersburg from the Meteorological Expedition at the Mouth of the Lena reporting "all well."

Corrosive sublimate is gaining ground amongst surgeons and others as a most efficient antiseptic.

M. Pasteur's son-in-law has published a work in which he relates in much detail the history of the great Frenchman's discoveries, and furnishes many lively biographical anecdotes. The book is entitled "Histoire d'un Savant par un Ignorant."

M. Ferry has requested the Academy of Sciences to appoint three delegates to the International Commission which is to meet in Washington in October to determine the choice of a prime meridian.

At a meeting of the Scottish Royal Physical Society, held last week at Edinburgh, the geological structure and age of the Harz Mountains formed the subject of a paper by Mr. H. Mowbray Cadell, B.Sc., of H.M. Geological Survey of Scotland. Dr. Traquhair made some remarks on the fossil fish called *Megalichthys*, found at Burdiehouse, and said it was his belief that it was a different species from the *Megalichthys* of the coal-measures. An interesting paper was read by Prof. J. Cossar Ewart on "The Principles of Classification in Natural History." In drawing up a system of classification, it would, he said, be necessary to distinguish adapted from essential characteristics, and to remember that no arrangement could be natural if it was not genealogical. The system at present in use was a natural one, but it was somewhat disjointed. For its improvement a number of suggestions were submitted, it being claimed for the plan proposed—which was based on evolutionary principles—that it was more simple and philosophic.

The gift of the *Alert* to the United States for the use of the Greely Relief Expedition is a creditable act on the part of the English Government, and it has met with gracious and hearty acceptance. Many years ago, when the *Resolute*, abandoned by English Arctic explorers, had floated free and been brought by an American whaler to New York, the United States Government refitted her completely, and then sent her as a gift to the Queen. Quite recently, when the *Resolute* was broken up, her Majesty caused a very handsome desk to be made from her timber, and presented it to the American President. The best wishes of this country will go forth with the *Alert*, that she may add yet another chapter to Arctic exploration of which the two nations, but one people, may justly be proud.

At a meeting, last week, of the chemical section of the Glasgow Philosophical Society, the second triennial Graham lecture, prepared by Dr. Angus Smith, was read by Professor Ferguson, the subject being "The Life and Work of Thomas Graham, late Master of the Mint."

A memorial window has just been erected in Newburn Church to the memory of the late William and Thomas Hedley. The subjects chosen by the artist are "Noah and his three sons building the ark," illustrating the genius given to man, and the "Parable of the Talents," typifying the good use of the genius and wealth that man is blessed with. At the bottom of the [illegible] plate is the representation of a railway engine, and underneath are the words, "Drawing of the first locomotive invented by William Hedley, originally placed in Kensington Museum."

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor of the English Mechanic, *81, Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

> "I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clatter with this little pittance of his, will undertake to write the whole body of physicks: a vice from whence great inconveniences derive their original."
> —*Montaigne's Essays.*

THE RECENT AWARD OF THE R.A.S. GOLD MEDAL—THE AFTERGLOW—SCINTILLATION OF THE STARS AND MAGNETIC STORMS—REPORT OF THE HARVARD COLLEGE OBSERVATORY—THE MOON'S MOTION—THE GEOLOGICAL SURVEY OF THE HOLY LAND—MEASURING THE POWER OF A TELESCOPE—THE INTERNATIONAL INSTITUTE FOR PRESERVING AND PERFECTING WEIGHTS AND MEASURES.

[[illegible].]—The award of the gold medal of the Royal Astronomical Society this year to Mr. A. A. Common, for his results in celestial photography, will, I think, commend itself generally to astronomers as a well-deserved recognition of the large quantity of really excellent work done by its recipient. The great and lamented American physicist, Professor H. Draper, had previously photographed the nebula surrounding θ Orionis with very remarkable success; but his results were quite surpassed in the altogether wonderful production by Mr. Common which was exhibited last year at the March meeting of the Royal Astronomical Society (English Mechanic, Vol. XXXVII., p. [illegible]). Moreover, Mr. Common, in pursuing the photography of the stars and planets, has incidentally rendered services of a very high order to the theory and practice of the arrangement and mounting of large telescopes: his devices for diminishing friction in a great equatorial, and for insuring the rigidly equable motion of its driving clock, indicating mechanical abilities of the highest order. Mr. Common only affords another illustration, if such were needed, of the fact that all our best astronomical work, outside of the mere monotonous "grind" of meridian observations, is performed by men entirely unsubsidised by the State: whose aim is the pure and lofty one of the pursuit of scientific truth for its own sake, and not for what can be made out of it by advertising, quackery, and puffery.

In the number of the *Précurseur*, an Antwerp newspaper, for February [illegible], I find a paragraph of such interest in connection with the recent wonderful displays of afterglow, that I am tempted to translate it for reproduction here. It is anonymous; but I feel pretty sure that it is the production of an eminent Belgian astronomer.

"Twilight Illuminations.—The phenomena seems to diminish slowly. As to its explanation savants are at their wits' end. There are as many opinions as there are people. But we are authorised in believing that it was equally manifest towards the end of the 16th century. We read in the history of Titian's life, that when he died the entire sky appeared red. This appearance is shown in the painting by Robert Fleury, which figures in our modern museum, and which represents the death of the Venetian painter. We see in the distance Venice and the cupola of St. Mark, which seems enveloped in an immense conflagration, of which the glow rises towards the zenith. When Titian died, that is to say in 1576, Shakespeare was twelve years old. The phenomenon should have been, at this date, equally visible in England, and perhaps, as at present, all over the world; and it [illegible] have been under the influence of this recollection of the time of his boyhood, that the immortal English poet made Glendower say, in "Henry IV.," act iii. scene 1 (Here I quote, not from the French, but from Shakespeare himself): 'At my nativity, the front of heaven was full of fiery shapes, of burning cressets; and at my birth, the frame and huge foundation of the earth shaked like a coward.' Failing any meteorological observation at this epoch, these coincidences are curious, and there seems to result from them a strong probability that this is not the first time that the sky has clothed itself with this wonderful light." Now my object in quoting this paragraph is briefly this: A great deal has recently been said about the connection between the late remarkable chromatic phenomena and the eruption of Krakatoa in Java on the 27th of last August, and I am very curious to know whether any authentic account is extant of a volcanic eruption of any sort at or about the date of Titian's death? I know, of course, that Vesuvius was quiescent between 1538 and 1631, and that no noteworthy eruption of Etna occurred from the classical ages until 1669; but America was pretty well known at the end of the 16th century, having been discovered some 80 years previously; and it is conceivably possible that such an occurrence as the eruption of one of the volcanoes of the Andes may have been recorded by some voyager of the period, assuming such a thing to have occurred;—a remark which would equally apply to any violent volcanic action in the Eastern Archipelago of Asia, and, in fact, to such action in any observable part of the navigable globe. Do then, any such records exist? Will anyone who can spare the time, and has access to early accounts of voyages and travels look this question up? Its solution might render a real service to science. It is useless to hope for the existence of any meteorological records, properly so called. Meteorology was even in a more inchoate and imperfect condition at the end of the 16th century than it is at the end of the 19th —although, perhaps, this isn't saying much.

The mention of Belgium suggests to me to remark that M. Ch. Montigny, of Brussels, our first living authority on the subject of the scintillation of the stars, has recently made a most remarkable discovery, of which more will certainly be heard. It is pretty well known that the twinkling of the stars is materially aggravated by the presence of the Aurora Borealis; but M. Montigny has shown, by the comparison of a very large number of observations of the stars, with the magnetic records contained in the *Bulletin* of the Royal Observatory at Brussels, that abnormal scintillation corresponds with absolute accuracy in point of time with great magnetic disturbances; albeit no vestige of an aurora has been anywhere recorded! M. Montigny's observations were made with his singularly ingenious scintillometer, in which the telescopic image of the star is converted into a circle of light by reflection from a rapidly-rotating glass disc; just as an incandescent stick whirled rapidly round forms a seeming fiery circle. This question, however, is too important to be dealt with in such a fashion as as this; and I must hence content myself with the bare mention here of his latest advance in it.

Yet another annual report (the thirty-eighth) of the Director of the Harvard College Observatory has reached me through a friend, and once again I read Professor Pickering's account of the steady pursuit of the excellent and enduring work carried on by himself and his zealous assistants. Eclipses of Jupiter's satellites continue to be observed photometrically, and a very ingenious method of observing occultations and transits of the satellites has been devised by the aid of a double image micrometer. This enables the time of these phenomena to be determined within about nine seconds; which is less than the probable error of observing an eclipse by the old method. Charts of stars are in the course of preparation for the establishment of standards of stellar magnitudes. The meridian photometer continues in use, and its determinations of absolute stellar magnitudes seem to be the most trustworthy ever yet obtained. Variable stars have formed an especial subject of study, and excellent and instructive star maps have been obtained by photography. The parts of the report dealing with meridianal observations, the distribution of time, and the determination of the difference of longitude between Cambridge, U.S., and Montreal, demand no special notice, as they only refer to work akin to that performed at other observatories. It is interesting, though, to note the names of no less than six ladies as assisting in the reduction of the observations made with the Great Equatoreal, the Meridian Circle, and the Meridian Photometer. It would seem that the guarantee of an annual subscription of 5,000dols. for five years given in 1878 has now expired; and an attempt is being made to raise 100,000dols. as a permanent fund, of which 50,000dols. are already promised. In the nominal list of subscribers, by far the larger portion, both ladies and gentlemen, of those who contributed in 1878 reappear; and it is as instructive as it is gratifying to read such entries as "A Friend, 10,000dols"—and so on. How is it, I may once more ask, that we find these noble-minded Americans offering such munificent donations for the advancement of science? The answer is not far to seek. They know that every cent will be expended in the prosecution of well-defined scientific work of enduring value, and that their liberal gifts will not be misused for the private pecuniary advantage of any mere advertising quacks, but devoted wholly and solely to the carrying out of legitimate astronomical labours. I will not believe so ill of my own countrymen as to imagine that they would not be equally liberal if they had the same guarantee that their money would be honestly expended. How comes it to pass, then, that in this great nation a few wealthy men do not raise among them the annual sum necessary to keep the "Committee on Solar Physics" going? The reason is not far to seek. An appeal for such a purpose must be made to persons possessing more or less knowledge of astronomy; and astronomers know, to a man, that the whole thing is a mere quack imposture, originated and maintained for the personal benefit of an impudent advertising little ring. Mr. Mundella (whose knowledge of astronomy is probably about on a par with that of the cab-horse who takes him down to the House), and the equally learned permanent Officials of the Treasury may be "worked" by the Brompton wire-pullers to rob the nation annually for their benefit; but merely as a matter of course, the latter could not—and they know they could not—raise the amount which they divide among them every year from any set of men possessing the most rudimetary technical knowledge of the subject which they are supposed to be investigating.

Query 52998 (p. 525) is very nearly meaningless as it stands. "George" has apparently been reading an account or description of that inequality in the Moon's motion known technically as the Variation, in some book which explains it but hazily. Regarding the earth, for our present purpose, or the centre of the moon's motion, the action of the sun tends to retard her velocity from New Moon to First Quarter; to accelerate it from First Quarter to Full Moon, to retard it from Full Moon to Last Quarter, and to accelerate it from Last Quarter to New Moon again. This, however, is very far from being the only inequality. There are several others, which notably affect her place in the sky. As for the assertion that "the moon's motion is slower than the earth's:" this, as it stands, is mere nonsense until it is stated at what point such respective motions are referred. The earth is travelling round the sun at a mean rate of some 18·5 miles per second; an interval during which the moon only moves some 0·64 miles in her path round the earth. Turning to "George's" string of questions (unanswerable here) about the Tides, if he will reflect that the earth turns 27·32 times on her axis faster than the moon goes round her, any body following the moon must seem to travel from East to West. The number of minutes the moon comes later daily to the meridian do *not* represent the number of degrees of a great circle moved over by the moon in her orbit in the interim; because such motion is oblique to the equator, on which time is measured. The path of the moon relative to the sun is shown in a diagram of my own on p. 307 of Vol. XVIII. Your correspondent had much better get, and carefully read, Proctor's "Moon," published by Longmans; which you reviewed on p. 615 of Vol. XXVII. The Lunar Theory is one of the most difficult subjects to present in a popular form, with which I am acquainted.

In common with every geologist in England, I am most anxiously awaiting the publication of Professor Hull's results of his survey of Palestine, to which reference is made in your "Scientific News," on p. 533. To say nothing of his other discoveries, the mere establishment of the fact that at the date of the Exodus, the Red Sea and the Mediterranean were continuous, must introduce most remarkable changes in the current interpretations of the Jewish tradition. So startling an alteration in the physical geography of a well known region, within historic times, tends forcibly to show the fallacy of those arguments as to the distribution of the human race, &c., founded on the (supposed) immutability of the superficial configuration of the earth since man first appeared upon it.

The method of measuring the power of a telescope devised and explained by Mr. Holmes (in letter 22362, p. 534) is really only a modification of that invented by Mr. Schäberle, which is described on p. 145 of your XXXVIIth Volume. I can only hope that Mr. Holmes's mode of proceeding may prove more *practically* accurate than I personally found that of the American astronomer to be.

Very many thanks to "W. H. W." (letter 22364, p. 535) for his information as to the status of the so-called "International Institute for Preserving and Perfecting Weights and Measures." I read the paragraph (quoted verbatim in letter 23331, p. 514) on which my query was founded, in one of the morning papers; and it will be seen by reference to it, that it contains no indication whatever that the "Institute" is a mere association of astrological fanatics. Had I had the slightest suspicion that this was the case, I should certainly not have intruded on your valuable space by any reference to their vagaries. However, I think somehow that the British yard and inch will hold their own as metrical units without either the aid of the "buried cubit," or of modern perversions of the utterances of the Prophet Zechariah.

A Fellow of the Royal Astronomical Society.

SATURN'S RING.

[22396.]—Will any of our astronomical readers kindly mention if they have noted anything unusual or unsymmetrical in the appearance of ring C, where it is projected on the ball, during the present season?

Hardwick Vicarage, Feb. 22. **T. W. Webb.**

OCCULTATION OF VENUS IN THE DAYTIME, FEBRUARY 29, 1884.

[22397.]—I am somewhat surprised that none of your astronomical correspondents have directed the attention of your readers to this phenomenon, which to an observer with a very ordinary telescope must be plainly visible.

The accompanying computations have been made in haste: but I think they are correct:—

	h.	m.
Beginning Feb. 29	3	6
Ending ,, ...	4	9

Angle from vertex at beginning 45° toward east.
,, ,, ,, ending .. 115° ,, west.
Least distance of centres........ 8·4′

The above calculation furnishes a good example of the partially-graphic process, of which I gave a succinct account in a recent number of the English Mechanic. For such as desire to solve the problem after this fashion I give the accompanying elements:—

Lat. 53° 3s. N. Long. 8m. 41s. W.

	h.	m.	s.
Planet's Hour Angle..............	0	35	22 W
Value of 10 divisions of latitude —parallax scale.............			·282
Moon below axis of projection of parallel ..			15·25′
Reduced Horary motion in R.A...........			32·75′
,, ,, ,, Dec...........			9·4′
Sum of semi-diameters			16·4′

James Pearson, M.A., F.R.A.S.

Fleetwood Vicarage, Feb. 22.

JUPITER, SATURN, &c.

[22398.]—On the night of Feb. 8th I watched the occultation of 68 Geminorum by the moon, and noticed that the star appeared to lose much of its lustre about five minutes before it disappeared. Also at the moment of disappearance there seemed to be a little splash of the rays of light around it. Having watched many occultations, and seen nothing like it before, I thought it might be as well to ask if others had seen anything of them in this or other cases. On January 8th I had a good view of Jupiter, the shadows of the first and third satellites being on the disc at once, about 10.30 p.m.; also the red spot being central at the time, and easily visible with 5¼ Calver mirror, power 112. The two unequally-sized jet black shadows of the satellites, the ruddiness and width of the equatorial belt, and at times the faint colour of the red spot, with other details, forming a sight not easily forgotten. During a splendid display of the planet on Feb. 24th, about six o'clock p.m., definition beinng nearly perfect, and much detail seen with surprising distinctness, the next dark belt north of the great one was seen to be divided by a narrow bright zone, and an ill-defined black spot was noticed on the northern edge of the equatorial great belt, this latter, by the way, being a good distance from the planet's equator apparently. When the red spot first appeared the lighter shading to the south seemed repelled by it; but lately the stronger great ball north has been affected in the same way. On this evening I saw Venus for the first time through the reflector, and, certainly, the whiteness of the image and total absence of colour, and the great distinctness, were very pleasing after being used to a refractor.

Turning to Saturn, I saw there were two belts on the globe, the northern one being widest and shortest. Concerning this planet, will the rings be more open next year? as, after looking at a sketch by "F.R.A.S." in "E. M." for 1870, I despair of seeing Cassini's division so open near the poles of the planet as those depicted, unless it will be so. Respecting the reflector, I find that the out-of-focus discs seen with H-eyepiece are of different colours round the edges, the one away from the focus being bluish, and the one inside the focus orange. I put this down to the chromatic aberrations of the eyepiece, and suggest that it may be a means of testing any ocular for colour. Would "F.R.A.S." or others kindly answer the following:—Should a mirror or o.g., perfectly corrected for figure, show the disturbances of the atmosphere, smoke, &c., more on the inside of the focus than the outside? I ask this because, on testing my mirror on good nights, the ring systems each side the focus are alike; but the moment smoke, heated air, or bad atmosphere comes on, the rings inside appear to suffer most, the central spot swaying from side to side, and the rings keeping anything but circular or distinct.

On a good night lately I saw Epsilon Arietis beautifully divided, and could see the division nicely with 4in. stop. Afterwards tried Zeta Cancri, and at times could certainly see them divided, the smaller component being to the right. The two small discs of Sigma 2 Cancri being very nicely seen as well. With 3¼ Wray o.g., I never could see the small star following the Ring

Nebula in Lyra, but on Nov. 17, 1883, I saw it quite easily with the reflector, and also the Debilissima pair of Epsilon Lyræ very much easier than with [illegible]; but, on the other hand, the blue [illegible] of Kappa Geminorum I cannot see so well. This seems [illegible], but I think it is owing to the colour of the [illegible], which makes it less visible; though why it should be more difficult with more light in the reflector than with less light of the refractor, I cannot say. I may say, in conclusion, that star discs and rings appear as sharp and hard as with [illegible] first-class [illegible], which is very different to what I expected when I ventured to make the exchange from one to the other.

Walsall, Feb. 25. **F. T.**

ASCERTAINING THE MOON'S AGE ON ANY DAY OF ANY MONTH.

[22402.]—Your correspondent, Major Trusswether, reminds me of a schoolboy who, when he cannot make his sum in arithmetic give the correct answer, concludes that there must be some error in the rule by which it is governed. As you have inserted his unfounded objection, will you kindly make room for the correct solution:

Question.—What is the moon's age on Jan. 1, 1884?

Here January is to be taken as the 11th month of the year preceding, reckoned from March. Also, 1883, divided by 19, gives remainder 2, and this, multiplied by 11, gives 22.

Hence we have	22
The third part of the century	6
The fourth	4
The number of months from March	11
The day of the month	1
The number	8
	52
Subtract the century	18
	34

or, rejecting multiples of 30, 4. Hence, the moon was four days old.

P.S.—The error by this method may amount to one day or two days at most, arising from the fact that the moon of the calendar is not the actual moon of the heavens. In this case, for example, there is an error of a day.

James Pearson, M.A., F.R.A.S.

Vicarage, Fleetwood, Feb. 22.

GRINDING EYEPIECE LENSES—DIALYTE TELESCOPES.

[22405.]—Your querist will find that the lens will not come up spherical if it revolves in the lathe; the lens should be held in the hand by its holder or stick; it should be worked against and with the motion of the lathe alternately. It is an advantage to the operator, whose experience is limited, to have a sunken tool, say one-fifth the diameter of the tool at its widest part; this should be in the centre of the tool. A polisher of best quality sealing-wax, in which a small quantity of rouge has been mixed while melted, will be found good. This should be stuck upon a metal chuck and turned carefully to the gauge. Washed rouge or putty powder and water should be used to polish with.

Mr Capleton's [illegible] glass should make [illegible] lenses. The rotary [illegible], all considered, is the best. The edging is almost complete, and of course the disc is more valuable; there is very little risk. Power is wanted certainly. [illegible] say any glass-works where steam power is used would undertake the job reasonably.

Our friend Mr. [illegible] has not, of course, noted the following practical facts when he suggested [illegible] as a reasonable figure for a [illegible] set of dialyte lenses. [illegible] should be of good figure. Now nearly all plate glass gives [illegible] images if worked true. I am of opinion this is owing to the pressure in making [illegible]. The surface then must be figured to counteract this, or I suggest [illegible] in the direction, so that the axes may be crossed. Lenses in the shape can be made cheap enough, but I think the form deserves the best that can be got. These will not be obtained for the price named.

Prismatique.

LATHE SCREWS—"UNLIMITED LIABILITY LATHE."

[22406.]—Your correspondent "H. [illegible] M." (letter [illegible]) remarks that he has heard nothing lately of the progress of the inquiry undertaken by the Amateur Mechanical Society in reference to lathe screws—I prefer this description of what is proposed to his own—and asks "What stops the way?" To this question I am sorry to reply that the witnesses themselves are the persons in fault—that is to say, that until I get about [illegible] answers to the interrogatories [illegible] I do not think the council would consider that they have sufficient evidence before them to warrant a decision. I hope you will allow me to take this opportunity of appealing to those members of the A.M.S. who have not yet sent in their answers to do so with as little delay as possible, and to say that if in any case the questions have been lost or mislaid, I shall be happy to send another copy on hearing to that effect.

I should like, whilst I have my pen in hand, to make an observation on the paper in your issue of February 15th, entitled an "Unlimited Liability Lathe." The writer has, no doubt, tried the plan he suggests for turning large work, such as a table top. I have not; but, seeing that the gouge would have to be held almost at arm's length for a great part of its traverse, and that the surface to be turned would be twice its usual height from the lathe bed, I should imagine it to be a work of extreme difficulty, if not impossibility, to produce a smooth and level surface, plank way of the wood, in such a position. To work a moulding on the edge would, of course, present less difficulty; but even for that I should prefer the alternative method of allowing the work to overhang the lathe-bed, which, in the case of a traversing mandrel especially, would not be difficult to arrange.

If an amateur is content to limit the size of his work, so that its semi-diameter shall not exceed the height of centre of his lathe by much more than three inches, he will find no better plan than the employment of lifting blocks, which may be of wood, to raise his lathe-head. My own, which are of cast iron, planed up true on all sides, measure 8½in. by 3in. by 1½in., and with them I can raise the centre of a 5in. lathe to 6½ or 8in., according as they lie on their edges or flat on the bearers, thus enabling me to turn up to nearly 16in. in diameter. I use with them a larger and higher tee-rest, and an extra long holding-down bolt: the former I had made, and for the latter I remember using a piece of iron rod on which I cut the necessary screws with a chasing tool that fitted the thread of the original bolt. That was, however, some twenty odd years ago, in what Mr. Burnaby would call the "pre-aliquot period," when, sad to say, we never troubled our heads about the precise pitch of the screws used for such purposes, and yet did some tolerable work! A pair of iron blocks, such as I have described, are useful for a variety of purposes besides that named above: they serve as weights; laid on a piece of glass paper spread upon the bench, I use them as rectangular guides for rubbing down the edges of small cabinetwork; and heated, they act as cauls for veneering small flat work. I fancy the amateur who follows Mr. Lukin's design, and puts his tray on the top of a pedestal 12in. high, will find that he has produced a very uncouth piece of furniture. I have a "dumb waiter," such as he intends to describe, made of some kind of ware, in which the underside of the 15in. plateau is only raised 3in. from the table. It answers its purpose and looks well.

T. W. Boord.

14, Berkeley-square, Feb. 19th, 1884.

[22407.]—The supposed difficulty does not exist. I can and have turned with ease a 15in. disc on my own [illegible] lathe in a vertical position by reversing the headstock, rigging up a high rest from the floor, and, of course, running the lathe backwards (or you will unscrew the chuck). I have used the fastest speed but one, and it quite suffices; and with the next or the very slowest speed I could turn 15in. without difficulty. But you want for this someone to tread for you, as you should be on the wrong side of the lathe, though I have managed it alone. To do away with this awkwardness I proposed the horizontal arrangement. If I drew the cord wrong, or the chuck was put on eccentrically, I did not intend it. The general notion was, I think, quite clear. A big disc acts partly as its own flywheel. No [illegible] of lathe is needed, only a screwed hole in poppet. It is no mare's nest—a pin in the rest, such as brassturners use, will no doubt make it easier to steady the tool. My 5in. lathe bed is gone for some fittings to be made, but as soon as it returns I shall use it as stated. If a disc can be turned of the size named, when running in a vertical plane, it will do just as well the other way. My flywheel has three speeds on the rim, and one for still slower motion. It is not specially heavy, but runs well on a stud. Ordinary [illegible] work is easy, and will be still easier, as I am having a new hand mandrel and collar fitted. My usual mode of cutting out a round disc is to put a square piece of board in the lathe with corners sawn off unless it is a small piece, and then to bring a sharp parting tool against its face, just within the largest possible circle. The outside rough part then comes off as a ring, and the edge of the disc is also tolerably smooth. This does away with the [illegible] of roughing down projections. The outer part left [illegible] may come in for beehive boards, which I make in that way, of mahogany, using the [illegible] for other purposes.

I am not at all sure that I shall not have a special short poppet made to stand on end, with [illegible] to fit the chucks, and a single-speed pulley. I [illegible] all arms to [illegible] to take the [illegible] [illegible]. This would improve matters, and save removal of the headstock, but it is the principle of a horizontal lathe for large discs which I specially wished to suggest. Observe that an 18in. disc only projects 9in., so that you are not obliged to stand back much further than usual.

O. J. L.

THE UNRELIABILITY LATHE.

[22403.]—No wonder W. A. Barber utters a mild protest against the utterly unpractical suggestions contained in the article he alludes to. It is characteristic of the author, and highly instructive to be taught the value of the ready "Yes," which the confiding inquirer receives, before he is started on the best road to "*How not to do it.*"

The points "W. A. B." refers to are quite beneath the notice of a "practical mind"! I do rather think it would take a 3in. head to turn a 2ft. table-top pretty evenly in every single part. First, we have the band on the largest speed of driving-wheel to smallest on mandrel. Those who have ever turned a 10in. to 12in. bread platter can form some idea as to the ease of doing it even on a 5in. lathe with the speed by no means at the highest. What will it be on a 3in., at edge of a 2ft. circle!

Next, we have the mandrel-head, whose frame is specially designed to give the greatest stability when axis is horizontal, cocked up on its end, held by a single bolt—in what must be a very shaky manner, even supposing there is the special bracket fitted to it. On top of this card castle we have our work fixed—probably at a height of 9in. to 12in. from the bed—and we ask the afflicted lathe to do its work to our satisfaction.

It must, too, be remembered, to make insecurity doubly insecure, the tool is to be supported on a rest which must rise more than the 10in. or 12in. above bed, and yet has only a 1½in. or 2in. socket to steady it.

If there are none of these self-evident defects in the plan, the need for guide-pulleys, and the amount of extra power absorbed in leading a band as shown, would be enough to condemn it for such a purpose.

And what is all this "much ado about nothing" when you get beyond desire to produce something novel? *There is nothing.* The work specified could be done in the old-fashioned way by turning the head, and rigging up a very simple rest, the back of a kitchen chair has more than once served such a purpose, and done its work well, which is more than could be said of this troublesome, and I imagine, completely unsatisfactory fixture.

Fredk. Carre.

BEE-KEEPING.

[22404.]—The bee-feeder mentioned by J. Perry, letter 22371, is a good one for rapid feeding, but not near so good as a bottle feeder, if well arranged and managed. I have used both very extensively, and much prefer the bottle with a graduated perforated cap [illegible] wood block, with slit [illegible] for regulating the quantity to be taken, with which I have no difficulty in either giving one hole very slow or eight to ten holes for rapid feeding.

I will now give my objection to the feeder mentioned, which is known as the float feeder. When new it works well for a time; but the syrup causes the float to warp or swell, when it catches either against the hole or sides, and sticks either up on one side or else when down, and in pouring fresh syrup in it goes [illegible], instead of [illegible] through it sinking, and if the bees are in at the time they get drowned, or stick together, causing a loss of bees, and if not to ease it, the bees get under the float, and get served the same.

I believe J. Perry and "[illegible] H." are like many others—they have read and studied "leaflet and bee-books," but when putting the [illegible] of some of the best bee masters into practice, are not sufficiently careful to attend to the [illegible], and thus fail and lay the blame on the wrong shoulders.

I was glad to see Mr. Abbott's letter, and wish he would contribute an article or two this spring. It could not be done by a more practical or better person, and I should be very glad to give place to him or any other such authority.

It might interest "[illegible] H." to know that the only bee-book I use is "Modern Bee-keeping," and I got more useful information from the "Leaflets" [illegible] that my plan was to read them carefully, then follow their teachings in all points, and by so doing I gained experience through practice.

I should have referred "[illegible] H." to them, only for what he said about them, and because I have often recommended them through the "E.M.," and do not like to be always pushing them before your readers; but the information I gave is quite clearly stated in them.

I shall be glad, as far as I can, to answer any queries of general interest during the coming year.

There is no mistake in the word [illegible]. I say [illegible], because I cannot get [illegible], and I do not think there is any necessity for thinner where wide [illegible], with [illegible] between. I put [illegible] and have the [illegible] across the entrance.

Movable bottoms are not required when you have plenty of length so as to move bars about for cleaning floorboard, &c.

I have hives with double walls all round, and double and movable wedged floorboards, in use; but think the others quite as good: they are all my own make. I think the South of Ireland a good place for bees, and hope "G. J. H." will succeed well this year; but much depends on the season as well as the *hives*, for if we do not get honey-producing weather no kind of hives will do well.

I have never tried the Ligurians; there seems to be such a difference of opinion amongst bee-masters as to their value, and only being a poor man I do not keep bees for pleasure only, but for profit. A friend of mine near here bought and introduced a queen, but did not succeed well with them; but I cannot say, having had nothing but the British Blacks. I have often raised queens, introduced them, both by grafting queen cells, and also, when mature, have transferred, deprived, united, divided, driven, rescued and built up condemned bees into good, useful stocks, and many other operations connected with modern bee-keeping, and, around here am called the beeman.

J. I. S.

BEE-KEEPING—FEEDERS.

[22405.]—The feeder mentioned by Mr. Perry is, I believe, very good for feeding up for winter, at least one on the same principle; but square and larger is first-rate for the purpose, as I have found by experience; but I do not know if it will answer well for stimulative feeding. If Mr. Perry means by "the bottle plan of feeding,"—turning a bottle of syrup upside-down on a piece of tin, and then slipping it on to a piece of perforated zinc over the feed-hole, I like it quite as little as he does; but there is another plan of bottle-feeder which, I think, by far the best for stimulative feeding, and I will describe how to make it. Get a large-mouthed bottle (I use marmalade bottles); make a tin cover like the cover of a canister, to fit it closely; mark a circle round the cover a little way inside the neck of the bottle; make a number of holes, say, 10 to 12 at equal distances on half the circumference of this circle. Get two square pieces of thin wood, say, ⅜in. thick, and make a round hole in them into which the cover of the bottle will fit, so as to turn round easily; get a piece of tin a little larger than the cover of the bottle, mark a circle on it of exactly the same radius as that marked on the cover; make the same number of holes on half the circumference at equal distances, which will be at exactly the same distances as those in the cover; put this piece of tin between the two pieces of wood, and tack them firmly together, taking care that the circle on the tin is exactly concentric with the holes in the timber. Now, on putting the neck of the bottle with the cover on it into the hole in the timber, you can in the first instance place it so that no hole in the cover will be opposite to one in the stage; you can now turn it round a little and bring one hole of each together, turn a little further and you will have two holes open, and so on till you have any number you like. Now, by making radial marks on the timber of the stage exactly opposite the holes in the tin and numbering them, and by fixing a little pointer or index opposite the first hole in the cover, you can manage so as to see at a glance how many holes are open, and increase or diminish the number as you think fit. The hole in the underneath piece of wood may be a little larger than that in the upper one, which fits the cover of the bottle, and the holes in the tin in the stage may be larger than those in the cover of the bottle.

I have described a rough home-made article, just as it was made by my son; but I cannot conceive anything more efficient for the purpose of stimulative feeding, or more easily managed. If Mr. Perry cannot make it himself, there is a feeder on the same plan known as "Green's Feeder," and also "Neighbour's Stimulating Feeder," sold by dealers in such things. I have used both kinds of feeders, and shall continue to use both. I would not think of using the bottle feeder for feeding up in autumn, and just as little would I think of using the float feeder for stimulative feeding; but I do not say that it could not be done, for I don't know, having never tried. I can speak from experience about feeders, as I had a great deal of feeding to do, most of my stocks being formed of "condemned bees," driven late in September without any comb or brood to transfer, and the remainder being swarms which required a good deal of feeding in the bad weather we had last summer, and nothing could have been more successful. My bees are out every day that is at all fine, and are now taking in pollen from crocuses, as well as from some other sources—I dare say furze. I first saw it with them on the 17th February.

G. J. H.

Erratum (letter 22372).—I find that the mode of Ligurianising mentioned by me at end of letter 22372, p. 536, is not taken from Mr. Raynor's pamphlet, but from "Abbott's Leaflets," No. 3, on Ligurianising.—G. J. H.

[22406.]—Several correspondents have asked lately for information about bee-keeping on the bar-frame system. I have tried this plan, and will give the results obtained. I must first state that I was very much prejudiced in favour of this plan. I determined to commence on the smallest scale, so in the early part of 1882 I procured Mr. John Hunter's "Manual of Bee-keeping," and thoroughly studied it. I came to the conclusion that the cheapest hive with which this system could be effectually worked was Neighbour's "Modern Garden Hive," so I ordered one, price 25s., besides carriage from London, which with 2lb. of "comb foundation" and "smoker," made the sum of 37s. I then bought an early swarm for 15s.; these, owing perhaps to an unfavourable season, produced no surplus honey. In the early spring I commenced to feed: they took two stones of sugar, cost 8s., tin for feeding 6d.; this makes a total for one hive of £3 0s. 6d. for the year, with as yet *no return*. This brings us to the spring of 1883; then my only necessary expense (I bought other things, such as a supply of American sections) was another hive, and the old stock having become strong through early feeding I divided them, as per instructions; this was successfully done; the bees worked when the weather was fine, and I anticipated a profit. The result was: no work done in the supers, and on examining the interiors of the hives, No. 1 was found with no honey to spare; No. 2 being pretty full, I took two bars, replacing with empty comb foundation. Yield of honey, 4lb.; value, 4s.

Here we have a return of 4s. for the outlay of as many pounds, besides time given at intervals over a period of a year and a half. Compare this with the glowing accounts of bee-keeping as given by some other writers. It will, I know, be said that the seasons have been exceptionally unfavourable. This I grant; and I retort that the very rosy pictures given on the other side are, as far as they are facts, quite as exceptional. Now, as to the hives themselves. They certainly cannot be called cheap: the price is at least enough to pay for good materials and workmanship; but do we always get these? During the fine weather, a short time ago, I thought it would be a good opportunity to see how the bees were going on. I found No. 2 all right—but No. 1! The faulty roof had opened at the joints, let the rain in, and—well—I have *one* stock of bees! The cover of No. 2 showed its quality earlier, and I had it pitched inside; otherwise I should probably have had no bees at all.

The above are the facts in my case. My opinion is, that *profitable* bee-keeping is impossible with anything like the original outlay at present necessary for the bar-frame system. Those who reap the profits are the dealers in the hives and apparatus.

I will, in another letter, give an account of a plan, though not yet tried, by which I believe straw skeps may be used, the bees not killed, and the bee-keeper paid for his outlay and trouble.

W. A. G.

[22407.]—I am glad to find that the correspondence on bee-keeping is reviving, and with "G. J. H." I hope we shall have the results of "real practical experience," whether it be amateur or professional. Bee books, though exceedingly useful and necessary, often fall short of what the would-be bee-keeper expects to find them. I have read several, but some of their statements I cannot accept. For instance—what weight of store will "winter" a stock? Now I have had the experience of many years among skeps, though only since last year among frame hives, and I have found that when a skep and contents weighed 21lb., the bees in it wintered well, and put out a good and early swarm. And even on less than this I should have little fear of their having plenty to carry them well into the ensuing spring, unless exceedingly mild weather in January and February causes them to fly when they ought to be at rest.

I well remember, some dozen or more years ago, an exceedingly good honey harvest. Nearly every hive was full, and consequently some much heavier hives than usual were left as permanent stocks for the next year. One of these, a very heavy one, having a numerous colony of bees, was expected to do well, but, on the contrary, it proved the worst in the lot. The bees having plenty of stores, were careless about gathering more, and spring being over, the summer was cold and wet, preventing their doing much when the store was exhausted. Hence, the colony proved really worthless. Now, I am far from saying that excess of stores was alone the cause of this; but, though I have since wintered some scores of skeps, I have taken care never to leave an abnormally heavy one. Better, far better, have too much than too little; better still, have no more than is necessary.

Orderic Vital.

BEES.—SPRING TREATMENT, &c.

[22408.]—Knowing that many stocks of bees in this country are now, owing to the mildness of the weather, breeding rapidly, I wish as a bee-keeper to give a few hints that I feel sure bee-keeping readers of "E. M." will not regret giving their attention to:—

1. Make it a rule early every spring and every autumn (on as mild days as possible) to make a quick and thorough examination of all your hives; clean their floorboards with a knife, and with a stiff brush brush all your hives clean and destroy all insect enemies, such as spiders, moth, earwigs, woodlice, &c., that may be found on or near them. Do not expose your hives to the air longer than you can help during the examination, &c., or you may chill the brood.

2. Feed such stocks as you find really need it, and take especial care of such as you find have a small number of bees in them, remembering that such stocks will find it hard to keep their hive up to the right heat for breeding, &c., and should therefore have their entrances made smaller and extra covering put on. Keep a sharp look-out for queen wasps, and destroy all you can find.

3. In a mild winter like the present bees breed more than in cold ones, therefore care should be taken not to have their entrances too large, and that they have sufficient covering on to prevent the brood in them from becoming chilled should the present mild weather be followed by a very cold spring. Remember that hives that are breeeding consume their stores rapidly, and although breeding ought not to be encouraged too soon, for fear of a return of winterly weather, care must be taken not to let your bees and brood die for want of food. Should their stores be small, they must be fed moderately.

4. In feeding your stocks in early spring, do so if possible on a warm day; if a cold cutting wind is blowing, such bees as are sure to be tempted out by your feeding will be chilled, and fall to the ground and perish. Avoid spilling food whilst feeding; it causes robbing if spilt.

5. Beware of dampness; keep your hives as dry as possible. I have an idea that a wet hive in company with a chilled brood has often helped greatly, if it has not really produced, foul brood, &c. Food given (in mild weather especially) greatly encourages breeding.

5. After you feel sure the winter has gone (and not before) encourage your bees to breed as much as possible; but always be on your guard against a spell of cold weather, and know that your best protectors are a small entrance and extra coverings. Small entrances are a good prevention of robbing.

7. Keep your stocks strong; use large hives, and put strong swarms in them; unite your swarms if they are weak; do everything to your bees in as quiet a manner as possible. Remember June is the month if you want honey, and as a last warning I would say should a cold spring follow the present mild weather, I hope such as have taken the hints I have endeavoured to give will not regret it when summer comes, and be none the worse for having heard the timely buzz of **A Working Bee.**

ELECTRICITY A MECHANICAL VIBRATION.

[22409.]—In letter 22305, p. 473, it was shown that when water and carbonic acid were produced by combustion, chemical affinity was an expansive force. Now chemical action also causes an expansion in the combustion of iron or zinc with oxygen, for the oxides of iron and zinc are less dense than the metals, and although the alteration in bulk is very little, yet the force required to produce it is in comparison very great, whether estimated by the heat obtained during the change from metal to oxide, or by the cohesion which is overcome. But there is a movement of oxygen as well as metal, and the oxygen must of necessity move faster than the metal, because it condenses from a gas to a solid, while the metal remains a solid, and almost without motion; and having regard to the combining weight, the momentum of the slow movement of the zinc will be overcome by the rapid movement of the oxygen, which will therefore give the most powerful mechanical effect. Again, when oxygen unites with hydrogen it moves into double its ordinary bulk, while the volume of hydrogen remains constant, so that in this case, as well, the oxygen is still the moving and consequently active mechanical agent. Also, E. Becquerel has determined by experiment that the amount of oxygen or of a similar substance, and not the metal, determines the amount of electricity in the galvanic action. The action of a battery may, therefore, be explained as follows:—If the liquid in a voltaic cell be vibrating each time a condensing vibration occurs, the oxygen will leave the hydrogen and combine with the zinc: this action will check the vibrations of the liquid, and produce a vibration in the zinc which will tend to expand in all directions, and traverse substances suited to its nature. The liquid, on the other hand, will absorb a vibratory force equal to what it has lost by the oxygen combining with the zinc. If the liquid is heated, then, because heat is a vibratory force, the vibrations become more rapid or powerful, or of greater number, and the action of the battery is therefore increased, which is known to be the case experimentally.

I consider this view of the battery is supported by the following circumstances:—

Water and some other liquids are mechanically carried through nonconducting porous substances by galvanic action, and when water is mechanically forced through such substances, galvanic action is produced; mechanical force and galvanic action are therefore directly convertible.

The stratified form of the electric light in vacuum tubes is an effect similar to the nodal points in the vibrations of sound. The passage of the current of a powerful secondary battery can produce both sounds and nodal points in an ignited platinum wire.

Priestley also noticed a difference in the tone of leyden jars when discharging, which he attributed to the surface of the jars, as well as the amount of charge, so that electricity has been connected with sound long before the present time.

J. Sutcliffe.

ELECTRO-MAGNETS.

[22410.]—"SIGMA" (23342, p. 519), asserts as I understand, that a magnet which is supporting a weight is doing more work than one which is not supporting any weight.

Let "Sigma" try the following experiment. Let him take an ordinary horse-shoe steel magnet; let him put on the armature, and hang a weight from it. He will find that the magnet, if undisturbed, will support the weight for an indefinite time. In the case of an electro-magnet, "Sigma" believes "that there would be a permanent reduction" in the strength of the current, thus showing that energy is consumed in merely supporting a weight. In the case of the permanent steel magnet, what is the source of the energy which enables the magnet to support the weight?

As a matter of fact, there is no greater cohesion between a magnet and its armature when a weight, such as the magnet is capable of supporting, is hung on the armature, than there is when no weight is hung on the armature. The analogy from animal muscles is entirely misleading. If fatigue is evidence of work done, the traveller in a railway carriage, and hosts of other people who get tired without doing anything, must get through an immense amount of work.

No doubt, if "Sigma" moves masses of iron in the vicinity of magnets, work is done, and the effect of this will be apparent on the galvanometer.

Prof. Sylvanus Thompson showed a very elegant experiment illustrating this in one of his Cantor lectures. A small electro-motor was connected in series with a battery and the lecturer's lantern galvanometer by means of which the deflection is visible to the whole audience. When the motor was allowed to rotate the deflection was less than when the pulley of the motor was held, thus indicating that a back E.M.F. was produced, and work done by the motor as "Sigma" has explained.

Should "X. N. X." try any delicate experiment with a Wheatstone bridge, he must be careful not to use an iron weight, whose movement in the neighbourhood of an electro-magnet might possibly induce currents, but a weight of wood or some other non-conductor. He will then find no indication of any increased work. He may, however, be quite satisfied with the result of his experiment described on p. 473.

Pem.

[22411.]—MY electro-magnet is one with thick wire, which, when excited by a good Daniell cell of large size, has held 56lb; but as the cell I employed in my experiment, described on p. 473 was not a very strong one, I used a 28lb. weight only.

There was a momentary reduction of current at the instant of bringing up the keeper and weight to the magnet: but as soon as the keeper is at rest sustained by the magnets, the current resumes its original intensity. There is, indeed, no reason to anticipate any (permanent) reduction of current since the magnet holding the weight is not doing work. Work is only done by the current while the keeper is in motion, since work implies overcoming resistance through a certain distance. While the keeper is in motion towards the magnet the current is reduced, in consequence of the inverse electromotive force generated by its motion, as in a magneto-electric machine or dynamo. This is more easily shown experimentally by the use of a small electromotor, and, as the experiment is an easy one, let me advise those of your readers who are in doubt upon these fundamental points, to try it for themselves. I worked my motor by a battery of five Grove's cells, through a tangent galvanometer, the galvanometer and battery being at one end of the room and the electromotor at the other. If the electromotor was held so as to prevent it doing work, the deflection was about 45°, but if allowed to revolve and do work an immediate reduction of current took place, and the faster the motor revolved the smaller was the current. Thus when running slowly the deflection was 40° (current about ¾ of original current), and when allowed to run at full speed the deflection was only 28°, or the current about half of what it was at first.

I supposed that the error to which I called attention was merely the result of haste in writing: but it appears from "Sigma's" letter that he believes there will be a permanent reduction of current, and that he really means that a table on which a weight rests is doing work. The case of fatigue produced by muscular exertion in holding up a weight (though it might suggest an interesting physiological problem) is here a misleading analogy. Fatigue is caused, but not because mechanical work is done by a mere act of sustaining the weight: the weight must be raised in order to do work.

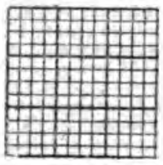
X. N. X.

MICROSCOPIC TEST OBJECTS.

[22412.]—I AM glad to see that "Monachus" (letter 23337) has stated this question in its simplest form, thereby bringing it within the limits of argument.

The proof by Prof. Abbe, that in order to be able to see a grating the dioptric and one first diffraction spectrum must be taken up by the objective, is also a proof that it is unnecessary to pick up all the diffraction spectra to see it.

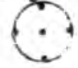
Let us imagine squares, strongly ruled on glass



12,500 per inch (linear), and inside each of these squares sixteen faintly-ruled squares.

An objective, N.A. 26, with axial illumination,

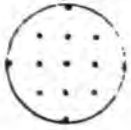
Fig. 1.



would show diffraction spectra, as in Fig. 1; the strongly-ruled squares would only be resolved.

Fig. 2 represents the diffraction spectra seen by an

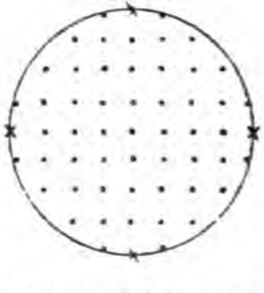
Fig. 2.



aperture of N.A. 52, the strong squares above being resolved. Fig. 3, aperture N.A. 1·04. The faint squares are now seen.

The spectra marked by a + are double ones, viz.

Fig. 3.



—the fourth order of the strong squares and the first order of the faint. Nothing further would be seen, even if the fourth order of the faint and the sixteenth order of the strong were admitted. Hence the true structure can be seen without taking up all the diffraction spectra, which, I infer, is the same thing as the "whole of the diffraction pencil," as stated by "Monachus."

The fact that various pictures may be produced by manipulating these spectra is not pertinent to this question, which differs from the original argument of axial versus oblique light, fully discussed in my last letter.

Having now stated all my view on this subject, I will not further trespass on your valuable space.

February 18th. **Edward M. Nelson.**

[22413.]—I AM glad that we have at last arrived at a point at which we can say Q.E.D.

Mr. Nelson in his first letter (22134) wrote: "If *S. gemma* is examined by this means, the true structure (which is far more beatiful) is revealed."

I invited Mr. Nelson (22151) to explain how he had come to recognise that with the objects of which he wrote there could be any determination of structure as "true."

Mr. Nelson replied at length (22203) with a statement of the reasons which had led him to realise the uselessness of oblique light "for the determination of true structure," and citing as an instance of such determination the appearance of places where chips had flown off the sides of a groove in glass.

I replied (No. 22261) pointing out the fallacy of Mr. Nelson's supposition that he had determined the true structure of his objects.

Mr. Nelson now says (No. 23336) that in writing of "true structure" he was not alluding to the "ultimate true" structure.

I have only two remarks to make on this.

The first is Q.E.D.

The second is that I hope our more advanced brethren will not overlook the moral of this correspondence, but will bear in mind how disturbing it is to our less advanced brethren to have incautious statements put forward which require so much hammering at to set right afterwards.

Monachus.

GLASS DISCS FOR REFLECTORS.

[22414.]—AFTER reading Mr. Wassell's excellent letters, in which he so carefully described his mode of producing reflectors, I am surprised that he is content to begin with the glass prepared in the manner he mentions. Surely if reflectors are worth all the trouble and care he appears to bestow on them, it would be wise to begin with a piece of glass as carefully prepared as possible. Now, if glass is nipped round the edge, it will be steened and strained more or less, which the most careful working afterwards would never get rid of.

"Nun. Dor.'s" directions for making the copper cylinders are quite correct. If they run true and firm, there will not be much difficulty in starting, and there is no reason why a dozen or more should not be going at the same time. One man would easily attend to the whole. I have used these saws for various purposes for 25 years, and can testify to the quality of the work. They should not be made air-tight. My experience is, that emery and water is best for stone, marble, or glass; oil and emery for metals.

Matlock. **W. Potter.**

CONCERNING LOCOMOTIVES — TO "HISTORIAN" AND MR. WOODWARD.

[22415.]—IT is not desirable to let this discussion degenerate into a mere squabble as to whether a certain expression was or was not a fair paraphrase of "Historian's" remarks, so we had best "agree to differ" on the subject. It would, I think, be very interesting if he would give tabular details of certain engines, *accompanied by distinct statements as to their actual performance*, and including the water evaporated and fuel consumed. As to the h.p. of engines, we seem to have pretty much arrived at the conclusion that the calculation I made on p. 386 was correct; but that it is not usual to express the power of engines in this way. I have to thank some gentleman who sent to me, apropos to a passage in letter 23344, a pamphlet concerning the claims of Mr. Hedley, as inventor of the locomotive. I am much obliged to Mr. Woodward for pointing out that one of the problems in query 52862 was set with impossible data: it certainly escaped my notice. I wonder if it was done purposely, or is a slip? There was a glaring error in the advanced paper for "Applied Mechanics," last May.

Wm. John Grey.

Elswick Science School.

[22416.]—I HAVE read the discussion on the horse-power of locomotives with much interest and my views coincide with those of your able correspondents, Mr. C. E. Stretton and "Historian." I can indorse the formula given by your correspondents as correct—viz.:—

$$R = 2 - \frac{V^2}{114} \text{ pounds per ton.}$$

If S = space passed over per minute in feet,

$$\text{Horse-power} = \frac{W.R.S.}{33,000}$$

W = total weight of the train in tons.

The above is, of course, information which has been supplied by Mr. Luis. But Mr. Grey will see that the above involves no elements which are connected with the dimensions of the engine pulling the train. It is here that the "uncertainty" comes in.

Perhaps Mr. Grey will understand this uncertainty better if I tell him that it is probable that no two engines built from the same drawings will run alike.

Perhaps I may make this clearer by quoting a passage from one of Mr. Reynolds' books:—

difference cannot, of course, be attributed to the drawings or the templates from which the engines were made. It is, for the most part, due to the putting of the parts of the engines together; for no two engines were ever put together geometrically alike; and even when they are very nearly identical in the erection, they may be, and have been, made very unlike by so simple a matter as the construction of the brick arch in the firebox. Arches may be too long, too short, too high, or too low. They may also be rendered unlike by following slightly different lines in cementing the smokebox—probably the most sensitive member about a locomotive engine. There are many other ways of explaining why a difference should exist between sister engines. It may be in the castings of the cylinders, in the copper of the firebox, in the valves, or in the chimney."

Again, although the boiler pressure of two engines may be the same, yet the effective pressure in the cylinders may be slightly different. This will, of course, alter the power which the engines are capable of exerting. The pressure in the cylinders cannot be calculated from the boiler pressure. It can only be approximated. For instance, with a boiler pressure of 140lb., the pressure in the cylinders will be about 95lb.; but the exact pressure is a matter to be determined by experiments made with the indicator. Again, one class of engines will exert more power and run better than another class, of practically the same dimensions, because they "steam" better, or run more freely.

I think Mr. Grey will understand, from the above instances, that there is a very large amount of uncertainty as to the power which will be exerted by an engine of any given design. It is, in fact, a matter entirely for experiment to decide if engines of a given design will work the traffic they are designed for. It is for these reasons that the power of a loco. is estimated in tractive force.

The formula used, which shows results coinciding with the results of experiment, is—

$$\frac{(\text{Dia. of cyl.})^2 \times \text{stroke}}{\text{dia. of driving wheel}}, \text{ all in inches.}$$

This gives the tractive force in pounds per lb. per sq. inch effective pressure in the cylinders.

It has been found by experiment that to attain a velocity of 60 miles per hour on a level, with 15 coaches (or say 150 tons, exclusive of engine and tender), requires a T.F. of 100lb. per lb. effective pressure in the cylinders. This has often been pointed out by Mr. Stretton. Mr. Grey might connect horse-power and T.F. by finding the work done in moving such a load at 60 miles per hour on the level from the formula given at the beginning of this letter; but although theoretically interesting, I am afraid the result would prove of but little value.

On looking over the earlier letters of this correspondence, I find an inquiry from Mr. Grey as to the speed that can be obtained from driving wheels of a certain size. I may add that the least dia. of driving wheel which I have known to run at 60 miles per hour is 5ft. 3in. (L.C. and D. and M.R. tank engines). On the L. and N.W.R. a 6-coupled goods engine (with the side rods connecting leading and driving wheels taken off), with 5ft. 2in. wheels, could only attain a speed of 59 miles per hour, owing, it is stated, to the wheels being too small to attain 60.

Meteor.

RAILWAY KEYS.

[22417.]—The recent decision of the Midland Railway Company to place the keys on the outside of the rails instead of the inside as at present, has called attention to the whole question of permanent way, and promoted considerable discussion in engineering circles. The advocates of the inside and outside systems appear to have been very equally divided, and very powerful arguments have been brought forward upon each side. The question is constantly asked: "What is the reason for the present change?" Your correspondent "Loco," p. 524, No. 52979, has endeavoured to find a cause, and states it is "*so that wheels will run longer without turning up.*" It is hardly necessary for me to tell your readers that such a reply is absurd, and does not throw any light upon the matter.

Previously to the year 1870 the Midland Company had adopted the usual plan of placing the keys *outside* the rails; at that time it was found that the keys so placed came out of the chairs to a serious and dangerous extent. On some occasions three and even four consecutive keys were found out of the chairs, the result being that there was nothing to prevent the train from "spreading the road" to a dangerous amount, and cases did occur of vehicles leaving the line in consequence. The company, therefore, in 1870-71 considered that the *inside* position was to be preferred, as if the keys should come out there would be no danger, as the gauge of the line was maintained by the outer jaw of the chair, and not by the key. It was also considered that platelayers would more conveniently examine their lengths of permanent way when they could see the keys of both rails at one time.

The *inside* keys gave general satisfaction for several years, and there was no doubt that the system made a good strong road; the question is whether it was not too strong—amounting to rigidity, for since the weight of engines and rolling stock has increased, the number of broken chairs has become a serious matter for consideration.

Complaints have for a long time been made that Midland trains appear to run "harder" and more "noisily" than those of some other lines. One cause of "noise" is doubtless to be found in the ballasting.

Your readers will have observed that upon many railways the sleepers and the bottom side of the rails are covered with ballast; this tends very materially to insure quieter running; but, on the other hand in rainy seasons it keeps the permanent way in a wet state unless very well drained. The Midland Company adopted the plan of never allowing the ballast to cover the sleepers, thus insuring a dry road, but at the same time a noisy one.

This Company has, therefore, decided upon the report of its new engineer (Mr. Langley), to place the keys on the *outside*, considering that the introduction of wood between the rail and chair will provide the necessary elasticity which is so evidently required to prevent the continual breakage of chairs. The level of the ballast is also to be raised, with a view to reduce noise.

Experiments are now being made to obtain some really good system of preventing keys working out of the chairs. Several plans are being practically tested upon parts of road with the heaviest traffic. So far the best results are given by chairs which are "roughed" or have teeth on the inner side of the jaw; it is, therefore, probable that this pattern will be adopted.

In shunting yards and sidings the ballast should always be raised (both between the rails and in the six-foot way) to the level of, or very little below, the top of the rail. Many guards and shunters are annually killed and injured by catching their feet against the top of the rail when stepping under the buffers of waggons, either to couple or uncouple them, and, of course, any slip made at such a critical moment is almost certain to result in serious consequences, and as the raising of the ballast to the required level is such a very simple and inexpensive matter, it is to be hoped the companies will do all in their power to make shunting as safe as possible.

In conclusion, I may mention that I have a number of diagrams and details of permanent way (which form part of a paper read by me, and of my pamphlet on permanent way), some of which, I hope, at no very distant date, to place before the readers of the English Mechanic.

Clement E. Stretton, C.E.

Leicester, February 23.

ATTRACTION BY SOUND.

[22418.]—I recently made the experiment of the attraction of light substances, such as tissue paper and gold leaf by the vibrations of an ordinary steel tuning-fork, and after repeating the experiment frequently, the fork become less active, until, by degrees, it had no perceptible effect. When, however, the fork was heated red-hot and well hammered, the attractive quality was again restored, so that when struck, it acted on gold-leaf very powerfully, producing an appearance similar to the electric attraction. The best effect is obtained when the prongs of the fork are rather flat, and not too much space between them. The attraction is occasioned by a mechanical movement of the air. As at present the phenomena of sound is again being brought forward, those of your readers who wish to succeed in experiments with the sound radiometer, &c., must take care that the tuning-forks they employ are made as elastic as possible with the hammer. Filing or grinding is objectionable.

J. Sutcliffe.

JOSHUA AND THE SUN STANDING STILL.

[22419.]—A few months ago there was a long controversy in your columns on the alleged miracle of Joshua commanding the Sun to stand still. I do not wish to reopen the controversy, but merely to inform your readers that in *The Church Quarterly Review* for January, a new and very able explanation of the occurrence has been given. It goes to show that Joshua prayed that both sun and moon might be silent—i.e., cease to shine (*dôm shemesh* are the Hebrew words), because he found that the hailstones, and the consequent darkness of the terrible storm caused more harm to his foes than the spears of Israel: hence he prayed that the darkness might be continued until the Amorites were overcome.

This philological discovery, which is perfectly tenable, dispels at once the astronomical objections to the miracle that have been so often made, and will give comfort to minds that are often sorely exercised by Scriptural statements which through lack of knowledge they cannot explain. As I said, I merely wish to give this information concerning this article in *The Church Quarterly Review* to those who in your columns conducted a lengthened controversy—one that now admits of so simple an explanation.

A. C. Smith.

CLEPSYDRA, OR DRIVING CLOCK FOR SMALL TELESCOPES.

[22420.]—While looking over an old book the other day, I came across what I thought looked a very simple method of constructing that expensive yet indispensable thing, a driving clock. The parts are:—Fig. 1. A, metal cylinder, stout enough not to get dented; B, floating box, containing weight (about 2lb.); C, angle iron, soldered or riveted on to cylinder, with pulley; D, brass siphon tube, with two cocks; E, thread to telescope. The dimensions are as follows for a 3in. or 4in. telescope:—Large cylinder, 2ft. high, 6in. bore; brass siphon tube, about 52in. long. I have just constructed a clepsydra like this, and find it drives beautifully accurately my 3in. telescope. Mine is constructed of sheet lead, and the whole thing, including labour, cost me 10s. There should be two cocks on siphon tube, so that when the right flow of water has been ascertained by trial, one cock may be fixed, while the other is used for stopping or working the machine. There should be a winding drum on eye end of telescope, to allow for lengthening and shortening thread. This I manage thus:—In Fig. 2 A is a winding drum, fixed on to and revolving round sliding tube of telescope, and capable of being jammed by slightly pushing in sliding tube.

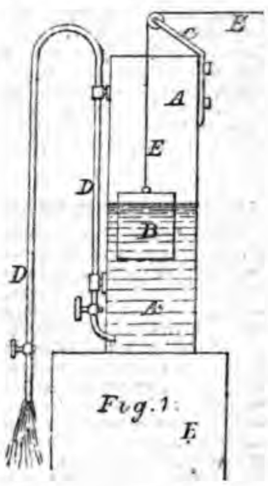


Fig. 1

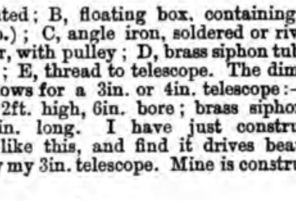

Fig 2

F. Hughes.

PUMPING BY SUCTION.

[22421.]—Though I did not dream that "Essar" either ignored or was ignorant of atmospheric pressure, yet his letter (p. 499) seemed to intimate the existence of some *additional* force at work; and this was why I used the phrase "as a *factor* in the working," &c.; am sorry I misunderstood him.

From the original note (p. 453) it seems plain that at or near the close of the upward stroke, the pressure of the atmosphere sustains the weight of a column of water 37ft. in height. It may be possible, but I should as soon expect to see that selfsame pressure supporting 33in. of mercury in the barometer. I should be as pleased as "Essar" to see it proved, and so shall wait to see what P. J. Davies may be good enough to tell us.

The pump so well described by "W. W. W." does not seem to have anything in common with the one mentioned p. 453.

"W. A. G." makes me describe "suction" as "a feat." The fact that he is unable to do the schoolboy task of reading correctly my letter, accounts for the illustration (the "baby") that so so naturally occurs to him.

Egstow.

GLACIERS.

[22422.]—Your able correspondent, "C. B. A.," in writing on the movements of glaciers, seems to me to have overlooked one most important factor—

viz., the internal heat or bottom warmth of the mountains. It is well known several important streams, such as the Rhone and the Rhine, are almost entirely fed by water running away from the glaciers. This melting of the ice of glaciers goes on strongest and quickest at their bottoms; in consequence, as the support of the superincumbent masses is taken away below and underneath, they must move. That this bottom warmth and consequent melting away of the glaciers is at least a certain cause of movement is shown also by the difference in movement during summer and winter. In summer, the glaciers, particularly in hot summers, draw "up," almost visibly, the mountains, through the rapid melting away; while in winter, the longer and harder the frost, the quicker and farther they advance "down" the mountains. It will be seen, therefore, that the movements of glaciers are not simply as "C. F. A." has it, "downwards," but "backwards" in summer and "forwards" in winter, so that heat, the melting and freezing of the snow particles, must play a most important part in their movements.

F. W. H.

INGROWING TOENAILS.

[[illegible].]—Have a pair of pepper nail-scissors, and instead of cutting your nails in the usual way, cut them hollow. Work your scissors points on the centre of the nail, finishing, as it were, a half-moon shape, leaving the corners standing nearly to a sharp point. Do this and follow it up as your nails grow, and you will find the sides will soon grow out and keep out. Bathe your feet in warm water, with a little soda in, before cutting your nails, as it will soften them so that you can cut them easier. The above has been a blessing to me now for several years, and I would not deviate from it for any amount of money, for prior to it I had tried everything which has been named by your correspondents, and a hundred things more fruitlessly. Nature always makes an effort to fill up a vacant space, that accounts for the success of the remedy.

Fisher Shaw.

[illegible], Stanton-street, Newcastle-on-Tyne.

KETTLE BROTH.

[[illegible].]—The following is a palatable dish much used in Germany for invalids. Stale bread broken into a pint basin about three parts full, a piece of butter the size of half an egg, plenty of pepper and salt; pour on boiling water enough to cover the whole; put a plate on the basin, and let it stand about [illegible] minutes or more. This will stay on the stomach when few other things will.

R. L. Caplan.

This is the "kettle broth" familiar to North Devonians and others in the West of England, where, however, the dish is made more luxurious by the substitution of clotted cream for butter. If it were better known in districts where milk is dear, or not to be obtained, many a hungry child might have a cheap, good breakfast.—Ed.

THE TELEPHONE.

[[illegible].]—It seems a very strange thing that in these times a company can so completely monopolise an invention like the telephone, in the face of so much evidence to prove that neither Professor Bell nor Edison can claim priority of invention any more in this country than in America.

I was much interested in reading two letters upon the validity of the United Telephone Co.'s patents, which appeared in the [illegible], Feb. [illegible].

The first letter is from a well-known authority upon this much-vexed question, W. C. Barney, whom I feel sure is known at least by name to most of our readers. He states, "In 18[illegible] the following description of a telephone receiver:—'An electro-magnet in front of a brass diaphragm, with an iron button attached to the centre of the diaphragm.' This description was published in England," he states, in the above year. He also says "that the original instrument is in the possession of a friend, and talks as well as any Bell telephone."

This invention, if it can be upheld, would undoubtedly nullify Bell's patent.

Next in the order another claim of priority to Edison's [illegible] from the same [illegible]. I am also strongly inclined to believe that evidence is in existence that in 18[illegible] a transmitter for telephone purposes, consisting of a tension regulator in combination with a diaphragm, was made and publicly exhibited, by means of which [illegible] was heard in a receiver and the difference between the speakers' voices [illegible].

This [illegible] a very strong evidence against the claims of the United [illegible] receiver invented [illegible] there must yet remain some description [illegible]

Turning again to the second claim of priority in the case of Edison's tension regulator, if the transmitter of 1865 is in existence, surely there can be no difficulty in its being identified by some of those who saw it publicly exhibited in that year.

It surprises me greatly that with such a mass of information no one dares dispute the claims of the Telephone Cos. here; perhaps the late decision in favour of Drawbaugh may add new life to the flagging energies of our enterprising electricians, for on turning to another letter from an old friend of ours, Mr. H. B. T. Strangways published in the same paper, some startling facts are again disclosed. He states, "The Court of Appeal decided that the exhibition of the Glasgow instrument was a publication of that instrument, which is consequently free to the public."

How is it that it is impossible to get any of these legal instruments? I have written to most of the electrical firms in England and Scotland, but no one seems to know anything about them.

Mr. Strangways also kindly informs us "That the Bell patent is good for a particular combination of parts of which that receiver is composed, which are:—

"1st. A permanent magnet, which one of the judges said was adjustable.

"2nd. A coil of wire on the end of the magnet next to the diaphragm.

"3rd. A diaphragm of iron, or steel, or metal capable of magnetic induction held down all round its circumference."

Now all these particular combinations can be done away with, leaving a perfectly legal instrument capable of transmitting speech.

1st. The magnet may be made of a solid bar of soft iron magnetised by a coil of wire and a battery.

2nd. The diaphragm can be made of wood, parchment, or any other non-magnetic substance, and under this diaphragm a thin sheet of spring steel may press. The steel will be moved by the vibrating of the diaphragm.

3rd. The bobbin of wire and the diaphragm may be placed at opposite ends of the magnet without in the least interfering with the acoustic properties of the instrument.

Perhaps it might not be uninteresting to some of your readers to know of a transmitter which I have made, and which I believe is covered by no patent: it consists of a Grove cell of 4in. high, 1½in. wide, and 8in. long. In the outer cell are two plates of zinc so arranged as to be lifted out of the acid when the telephone is hung on a hook; and a thin ferrotype plate has soldered to it a thin sheet of platinum which dips only a very little way into the acid.

The battery stands in a wooden box, the top of which is padded all round with rubber, upon which the ferrotype plate stands.

One wire is covered to the zinc, the other to the platinum, and I found that this instrument spoke well when connected with a Bell telephone.

Another transmitter I am now making consists of an induction coil wound in two separate parts: the fine wire is in one layer in the shape of a spiral, and is fixed to a diaphragm, the other wire is also in a spiral, and is brought very near to the fine wire, from which it is separated by a very thin rubber band.

This, if successful, ought to make a very compact instrument. I connect the coil in the usual way: secondary to battery, primary to line and earth.

I have not yet tried it, so cannot answer for its working well.

C. C. MacCarthy.

Late Electrician, American Telephone Co.,
Rotterdam.

PRINCE BISMARCK AND THE VEGETARIANS.

[[illegible].]—I AM rather curious to know how the vegetarian authorities "dispose of" Bismarck. Some twelve months ago, and often since, they have endeavoured to show, but in a way not always satisfactory to thoughtful readers, that a great variety of cases support their theories. Two or three instances will illustrate my meaning. Feb. [illegible], No. [illegible], p. [illegible], a whole school became docile under their regime. But so did Squeers's boys, who helped to immortalise Dickens. No. [illegible], p. [illegible], a wild girl found in a forest, bounded from branch to branch, &c., like a squirrel; by eating flesh she lost all this nimbleness. In short, in my view, she had begun a process of development into a higher type. To reverse the argument, had the vegetarians sent a girl into the forest to acquire this [illegible] kind of nimbleness, she would certainly have been a very good example of reversion to an earlier type. But nearly the whole of the cases in these two numbers of the English Mechanic have a [illegible] ring about them, and are little adapted to [illegible] people in civilised life in England. About a fortnight ago the case of the Esquimaux was "disposed of" by selecting only such facts in his natural history as ran parallel with their theory. The material fact was entirely ignored: it is the climate he lives in which affects his diet. The [illegible] and [illegible] nature places within his reach [illegible] teach him to use without stint they are heat producers, and are indispensable to his very existence, short though it be. We have the highest authority for stating that what lowers heat in the body must decrease or lessen life. (See "E. M." No. 987, p. 543, No. 52673.)

Now, Bismarck eats like an Esquimaux, both in quantity and quality, raw ham, to wit. In addition to the Esquimaux fare, he has champagne mixed with beer and cigars to excess; besides other meals, always one long heavy meal late at night, &c. Moreover, it has required generations of Bismarcks, all of the Esquimaux type of eaters, to develop the one high power of Bismarck intellect now before the world. (See Dr. Busch's work on Prince Bismarck, recently published). Bismarck is nearly 70 years of age, but lives in a different climate from the Esquimaux, and his is just the sort of food the German soldier is made of—shinkin, bellona, beer, smoke. I should like very much to see *him* thoroughly disposed of by the vegetarians. If they can convince him that their prescribed course is the one he ought to follow in order to become good and intellectual, active and lively (see "E. M.," Nos. 934 and 935), then they need not write another word in support of vegetarian theories: these will at once pass into the region of accomplished facts. At present their depletory diet pervades and taints their arguments. If they are capable of some *tour de force* of this sort it might resuscitate for a time a belief in their vitality. Abel, "a keeper of sheep." Methuselah, Abraham, Ishmael, David, and Barzillai, who came to succour the latter when he was on low diet, all of whose wealth mainly consisted of sheep, and who must have experienced great vicissitudes in circumstances and health during their long lives. All the priests who received offerings and tithes of sheep, the innumerable hosts of flesh eaters who have passed away during thousands of years, have all contributed to develop a still progressive civilised world. Their spirits, I am afraid, are just now looking down with pity upon the vegetarians, and prompting the recording angel to blot out their vagaries with a "hot-water" tear.

J. D.

THE FRONT-SLIDE LATHE.

[22427.]—MR. CARRE's plan, in letter 23535, appears to me to have several disadvantages. First, the top or face of the bed is better with the channel between, so that rest and poppet can be easily fixed. Next it will be observed that the whole weight of the sliding attachment is carried by the lower V of the bed. This is fixing the support far below the centre of gravity of the attachment; and no matter how well a loose V piece is fitted, it cannot be so firm as a solid one. Therefore, I think it essential in an arrangement of this sort that the upper V should bear all the strain; and the lower loose piece will then have no duty beyond keeping the faces in proper working contact.

To obviate the oil and chip difficulty, why should not the front ledge of the bed overhang the V piece? I do not see that this would be any detriment to the efficiency of the arrangement.

The I form of bed is, without doubt, a very good one, but better, in my opinion, with a ⊥ slot along its upper face, to provide for fixing arrangements. The front ledge may be brought well over to protect the V, which, of course, must be cast sufficiently below the top to allow its angular edge to be planed. The angle block of the carriage may then be brought well up to the level of the bed.

I doubt whether this I form of bed will find favour with mechanics; many would doubtless prefer a light casting of the ordinary plan.

Can any other readers describe the arrangement of the V's, which may have been used in other beds of this kind, such as Cooke's, or that spoken of by Mr. Bear?

Orderic Vital.

Atomic Weight of Tellurium.—The atomic weight of tellurium not corresponding to what it ought to be according to Prof. Mendelejeff's theory of periodicity, M. Brauner has tried to determine it again with greater accuracy. The chief difficulty is to have the tellurium free from selenium, but this difficulty has been overcome, and the body has been obtained in beautiful crystals. As to Berzelius' method for the transformation of tellurium into anhydride, M. Brauner discovered that it is liable to considerable losses, and to avoid them he has had to take the most minute precautions. The process was controlled also by transforming tellurium into a new salt, [illegible], and by the synthesis of the telluride of copper, Cu_2Te. The results are the series of figures varying from 124·94 to 12[illegible], which would give, on the average, an atomic weight of 12[illegible], that is, corresponding to the theory.

The Southern New England Telephone Company are making arrangements to establish a through telephone line which will be over [illegible] miles long. The American Telephone Company are also making experiments with the view of connecting B[illegible] and New York.

EPLIES TO QUERIES.

their answers, Correspondents are respect- uested to mention, in each instance, the title iber of the query asked.

.]—**Lost Watch Wheel.**—P.S. I must not know what is wanted by this query, ıld like to know more.—X.

.]—**Soap Making.**—The common method ıg soap is by saponifying tallow and caustic and then with the aid of common salt ng the stearate and palmitate of potash corresponding soda compound. Pour into ng-pan strong lye, and then add the tallow. as it begins to boil, stir the mixture at s, and keep it well heated for about five The contents then become soap-glue. If ng has gone on well, the addition of fresh ıt to make no difference in the constituency ixture. It ought also to flow smoothly and and not in drops or irregularly. When the ation is finished, salt is added, and the is kept boiling until it assumes a greyish The mother liquor is then run off from the e, to which is added a fairly strong ley, applied. The boiling is kept up, fresh salt being added alternately. The mother again run off, and the soap is then placed oden box, so made that it can be easily o pieces. When cold, the box is un-, and the soap cut up as required.—W. Richmond, Bootle.

.]—**Engine.**—During a late attack of ill- iend sent me some of the back numbers of lish Mechanic to while away the time. In ber dated 26th October, 1883, I find a query, 03, put by "Young Engineer," and in the g numbers I find answers from several s (save the mark!), all of which answers m each other, and the whole of them wrong. prised me greatly. Now if it is not too late deavour to give a solution of the question d simple. Query, No. 52103—Compound —Data given:

n pressure by gauge = 60lb.
s of cylinders = 1 to 4
off in both cylinders = at ½ stroke.
– by gauge = – 13lb. = 2lb.
ck pressure.

to know:—Pressure of steam at points of n both cylinders. Back pressure of steam , final pressure in both cylinders, and No. sions, &c., &c.,

rs.—Firstly, High-pressure cylinders.

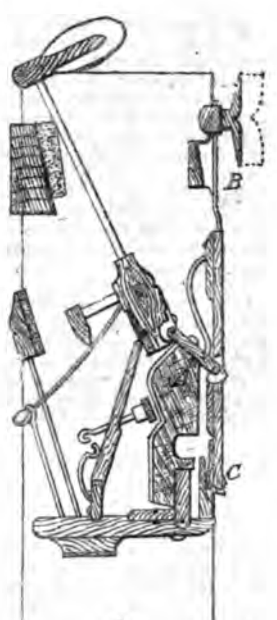
ressure = 60lb. + 15lb. = 75lb. absolute.
at point of cut-off = 75lb.
l pressure = 75 ÷ 2 = 37·5lb.
ressure = 75 ÷ 5 = 15lb., or at the
re of the atmo.
of expansions = 2

lly.—Low-pressure cylinders.
ressure = 37·5lb. absolute.
at point of cut-off = 15lb., and this
k pressure at h.p. cyld.
l pressure = 15 ÷ 2 = 7·5lb. – 2 = 5½.
essure = 2lb.
of expansions = 8.

+ 2 = 10 the total number of expansions, prove this 75 ÷ 10 = 7·5lb., the terminal as shown in low-pressure cylinder, and 2lb. = 5·5 as the final pressure exerted in -pressure cylinder; therefore "Young r" will see that he will have to cut off in a ylinder at $\frac{1}{10}$th stroke to obtain the same Having now answered all the questions, I w try to establish my position and the above But before I do so, let me remark that in such queries as the above you require no f stroke, no area of piston, and no measures. have seen above that our steam in the ssure cylinder at point of cut-off = 75lb. n thence to the end of the stroke it expands volume = 2, and its pressure will, there- 75 ÷ 2 = 37·5lb. This is its terminal , and the initial pressure in the low-pres- linder. In the following calculations for -pressure cylinder, and to save confusion, suppose the high-pressure cylinder to con- volumes and the low-pressure cylinder 8 of steam. Now, the initial pressure of m in low-pressure cylinder = 37·5lb., and lb. would, in ordinary circumstances, when t half-stroke = 37·5 ÷ 2 = 18·75lb. But ot so in our case, for, when the cut-off in -pressure cylinder takes place, there is 1 or half the volume of the high-pressure cut-off and left remaining in that cylinder ver pressure it may be, so that we have nes at 37·5lb., or 1 volume at 75lb., ıg 5 volumes in the high and low-pressure ; then 75 ÷ 5 = 15lb., the pressure at cut-off in low-pressure cylinder, and two expansions afterwards will give 15 ÷ 2 = 7·5lb. for the terminal pressure of the steam in the low-pressure cylinder. It must be borne in mind, however, that we leave 1 volume, or half the contents of the high-pressure cylinder behind at 15lb. absolute or atmospheric pressure; but this is no loss as it forms a cushion on being compressed by the forward motion of the piston, the same as in any other high-pressure engine cylinder. Had this 1 volume not been left behind the terminal pressure in the low-pressure cylinder would have = 9·376lb. Q.E.D. I hope I have now shown "Young Engineer" the way to find out the number of expansions, &c., that take place in compound engines for himself; and should it prove useful to him or any other reader, I shall consider my time while laid up not wasted.—Compound.

[52390.]—**Dynamo.**—The omission of a decimal point before the 6 will explain the seeming mistake. If your magnet is the double horseshoe form, the wire should be wound evenly on the horizontal part of the core, and not crowded against the pole-pieces. You have quite enough wire on.—W. H. E., Coventry.

[52509.]—**Piano Action for Under Dampers.**—Perhaps the simplest, though rather old fashioned, plan of under damping for cottage pianos, is to prolong the hammer butt far enough to impart a motion of about ⅛in., so that the damper may be well clear from the strings when the hammer is checked. The damper would be attached to a long regulating screw, which should pass through a slot in the sticker and out at the front, so that the damper could be adjusted to the strings without removing the action. A more modern method is by centring both hammer and damper on one rest (A). The damper is pressed against the strings by a spring, and may be regulated by bending the wire at B, always allowing a little play between the back of the damper stem and the rail. The motion is communicated by a small crank placed at the end of the hopper lever at C. The loud pedal acts by turning an eccentric roller in the hollow of the rail below A, or it might be by moving the action standards forward, as in the old Broadwood action, though, in that case, the buttons at each end of the action should be replaced by springs.—W. H. Davies.



[52520.]—**American Organ.**—Mr. Floyd places too much confidence in the perfection of his work and abilities, for he cannot reasonably expect to make an organ equal to an established firm which has experienced workmen of undoubted abilities. Mr. Floyd's experience and practice (I take him at his word, p. 543) are not sufficient to accomplish such results as he expects to arrive at, or such results as he has led us to suppose he has arrived at already. Those who only make one or two instruments occasionally cannot expect to make them equal to those who are constantly at the work, and who have facilities for learning beyond the reach of general amateurs. Mr. Floyd is wrong in supposing that I represented the art of reed voicing as a "mystery." I have done no such thing, but I have certainly represented it as a "difficulty," or rather an art requiring considerable practice and experience before any really good results will, or can, be attained. If Mr. Floyd can get a really good diapason tone from a set of reeds, I for one should be glad to know by what means he is able to get it—or, in other words, by what method does he voice his reeds, knowing, from his own assertions, that he never failed to obtain the real diapason tone? If this is true, then Mr. Floyd is wonderfully successful, and great credit is due to him, as he is then able to accomplish one of the most difficult tasks in the art of reed voicing, for in most organs there is a great deficiency of the true diapason quality of tone, which, in many cases, proves its difficulty of accomplishment. I, therefore, envy Mr. Floyd to some extent. How does he determine the difference in soundboards, if made to scale, and of the same material? He says that he has voiced reeds for two soundboards which, he asserts, are exactly alike, and that he has voiced all the reeds for each soundboard exactly alike, and yet each produces a different tone. Stop a bit, Mr. Floyd. Kindly change the reeds, or sets of reeds, on the two soundboards, and report the result. This will prove the correctness of his reed voicing. I am driving towards the truth now, and I trust Mr. Floyd will soon find out that there is something more in reed voicing than what he supposed, or supposes. With regard to cases influencing the tone, I believe our friend Mr. Floyd is right; in fact, I have proved it to be correct from experience.—G. Fryer.

[52520.]—**American Organ.**—As Mr. Floyd (p. 543) thinks I have been "unfair," I must perforce reply, more especially as my critic's want of acquaintance with his subject is likely to lead some of your readers astray. I think he would have been wise had he held his peace about his ability to voice reeds; for he now says that he meant he had succeeded in voicing reeds equal to those he can buy ready-voiced, but that "ready-voiced reeds by the best American makers are not in the market." But Mr. Floyd actually said on p. 433 that he had bought some of the very reeds which are acknowledged to be by the best maker, whatever Mr. F. may think, and he is evidently disappointed. Mr. F. does not tell us how he treated them, but proceeds to make any reed-voicer who reads his remark smile loudly at his notion that voiced reeds ought to be "tried and individually corrected in an instrument." Further down he tells us he can accurately reproduce the bend and twist, and he may believe me that if he can do that he can do all that he will ever get in the shape of voiced reeds from the "best-best" maker that ever tried his hand at it. If Mr. Floyd had ever tried the effect of finishing and tuning a set of reeds in one instrument and then transferring them to another, he would know that makers never pretend to finish or fine-tune reeds until the reeds are where they are going to stop. Mr. F. is self-contradictory, because he will have it, rightly enough, that the board and even the case have some effect on the sound; and what is more, he accuses me of seeming "to consider one board as good as another," when all I did was to laugh at Mr. Floyd's notion of makers turning out all the bad boards. I do not know how short may be Mr. F.'s experience, but if he would only think twice he would see that it is not an easy matter to try boards with a "well-voiced set of reeds," unless they are fitted with a set of pallets; and a maker having gone so far as that, is very apt to go further and finish the instrument. Something more must be done than "clamping on a windchest." I think it very likely that boards built up of several pieces of yellow pine will yield better results than those made of spruce; but I am quite certain that the difference is not so great as between reeds voiced by different men, and not so perceptible to the average ear. Mr. F. is mistaken in what he says about "Elève" (that gentleman did make some remarks of the kind, but it was in connection with a "harmonium pan"); and he also takes nothing by mentioning that "Joiner's" instrument has three rows of 16ft., because one can refer to p. 219, Vol. XXXV., and find that it is a two-manual, and that two of the three 16ft. registers are solo stops, and note also that there are four 8ft. registers to cover them, whereas in Mr. F.'s instrument there are two of 16ft. to one of 8ft. I should now like to know *how* Mr. F. has arranged his half set of 16ft. at the back, because it strikes me that an "ordinary three-row" board does not have a half-set stuck at the back; so that if Mr. F. has made the tubes and cut the pallet apertures, it would be interesting no doubt to some of your readers to have more particulars. It is no part of my business to criticise the work of distinguished makers of the American organ; but what Mr. Floyd says about his erring in "such good company" in no way affects my opinion. As he does not seem to know what the instrument he refers to really contains, I may tell him that it has three full rows of respectively 16ft., 8ft., and 4ft.; one and a half octave of 16ft. (Musette), and an octave of sub-bass (16ft.) The model is expressly stated by the makers to be a special one made to a specification supplied; and the simple fact that they have no other one-manual instrument with a 16ft. register in the treble, unless accompanied by at least two 8ft., ought to have opened his eyes. If he is satisfied with his instrument—if he really thinks it can be compared with the model he mentions—well and good. I understood from his query that he was not, and therefore ventured to express my opinion. Like the parrot, I am now sorry I spoke.—ORGANON.

[52549.]—**Unfermented Bread.**—Mr. Allinson will perhaps be glad to know that if the wholemeal flour is mixed with milk instead of water, the bread is much lighter and shorter, and altogether greatly improved. I have used it for some years. —L. C.

[52551.]—**Small Steel Balls.**—Seeing this remains unanswered, I offer you the best plan I know—that is, turn your ball as round as possible with ordinary hand tools in a lathe, then make a wood or lead chuck; turn same to receive your ball about a third its dimensions. Then you require to make a cupping tool from a piece of steel, one end to be turned perfectly true inside and out, just to cover about one-third of the ball, and tapered down to 1/16in. thick. Now take your steel ball, and put it into the chuck in lathe, holding it in with the cupping tool you have made, set on your lathe, and keep working your tool over as much surface of the ball as possibly, occasionally turning the ball round. See that your cupping tool is nicely tempered, and then you will get your steel balls quite true.—W. M.

[52626.]—**Wimshurst's Influence Machine (U.Q.)**—"J. J. H." is wrong in making the sectors so broad—¾in. at the broad end is quite enough. Then as to the two sectors on each plate being raised in the centre to just graze the brushes, this is not following the description in "ours," which, I think, was "that each and every sector must in its turn touch the brushes," and that the two opposite sectors on the same plate must touch, and afterwards end their touch at the same instant. All else in his description is right; he, however, omits to state the distance between the plates, and the number of sectors on each plate; the plates should run as close together as possible without touching. Twelve sectors on each plate for general purposes gives the best results; about 4½in. length of spark can readily be got with 14in. plates and good Leyden jars. I see in this week's issue "Another Amateur" gives very good dimensions for the sectors.—A MAKER OF MANY SUCH MACHINES.

[52654.]—**Point of Greatest Transverse Strain.**—Palmer's reply on page 543 refers to a beam with 4½tons 4ft. from one support, and 5½tons 6ft. from the other, to which a *rigid* mass is equivalent under the conditions he mentions. But the mass intended by "Querist" is a built-up one, like a stack of pig-iron, for instance, for which the calculation is so complicated.—J. S. C.

[52710.]—**Wheel-Teeth Calculation.**—I presume "Clockmaker" requires integral sub-multiples of his numbers. The best way to obtain them would be:—Resolve the given number into its prime factors (numbers divisible only by themselves and unity), and combine these to obtain the number of factors required. This rule will cover both questions of his; but he must notice two things:—1st, if the number of multiples he requires be greater than the number of primes, the problem cannot be solved; 2nd, a number may often be thus factorised in numerous ways.

Thus, 64,800 = 32 × 81 × 25
= 2·2·2·2·2·3·3·3·3·5·5,

and these may be arranged in a number of ways. If "Clockmaker" is familiar with elementary mathematics, he will find much that is useful in Todhunter's larger algebra (pp. 422, *et seq*).—EGSROW.

[52710.]—**Wheel Teeth Calculation.**—"Clockmaker" will find the following method a sure way of finding factors of any proposed number he may wish. Take the number 64,800, divide it and the successive quotients by 2, as far as possible (without remainder), then by threes and fives, &c., until quotient be only 1, as here shown:—

	Divisors.	Quotients.
	2	64800
a	2	32400
	2	16200
c	2	8100
	2	4050
	3	2025
f	3	675
	3	225
d	3	75
	5	25
	5	5
		1

Now, if three numbers be required, such that when × into each other shall produce such a product as the above, select such divisors × into one another as shall produce the most suitable numbers for the wheels. Such as the three top 2's (a) and one 5 at the bottom (b) × together: thus, 2 × 2 × 2 = 8, × 5 = 40; then a 2, a 3, and a 5 (c d e), thus 2 c × 3 d = 6, × 5 = 30; and, lastly, the remaining 3's and the 2, thus 3 × 3 × 3 = 27, × 2 = 54, which being × by wheel 40 = 2160, × wheel 30 = 64800. Another set can be selected, such as two 5's and a 2 = 50, four 3's = 81, and four 2's = 16; each set being involved become factors of 64800. As regards the latter part of this query, I think the above method will answer all that may be desired, but when the querist says four or five "multiples" I must ask of what? For a multiple is a quantity, or number, so many times repeated, as 2 + 2 + 2 = 6, the multiple, = 3 × 2 = 6, the 3 and the 2 being factors. But I will take it that four or five numbers are to be multiplied together, their product to equal a certain number. The above method will do it, though if the required number be a power, such as the 2nd, 3rd, 4th, 5th, &c., the root will be that number which when involved will become the required number, such as, for instance, 81 = 3 × 3 × 3 × 3 = 4th power. I wish some one else had answered this query; but finding it has got into the place it has, on page 546, I thought it best to get it out. See back numbers of "E. M.," Oct. 19, 1883, p. 157, and Oct. 26, 1883, p. 179.—X.

[52715.]—**Steam Launch.**—I have not time, just at present, to look through my back volumes and make a list of the places where "P. W. R." will find the information he requires. Life is so short, and "P. W. R.'s" knowledge evidently so little, that he really should not waste his time in what he calls "joking." If I knew how to drive a 12ft. boat at more than eight miles an hour through still water, I should take out a patent before publishing the news.—NUN. DOR.

[52715.]—**Steam Launch.**—If "P. W. R.," in his joking reply on p. 543, where he makes an attempt to ridicule "Nun. Dor.," had carried out his multiplication table, he would find that a launch or boat 12ft. by 3ft. would carry, say, 1 ton, and her ribs would be about 1in. square, and planking about ½in. thick. A ship 300ft. long, carrying 1,000 tons, would have, of course, ribs 1,000in. square, and planking 500in. thick. This is as reasonable as talking of a ship 300ft. long, 96ft. beam, going through the water at 192 miles per hour. "P. W. R." does not allow for the increase of friction as the speed increases. Water under pressure is a troublesome thing to deal with. No ship has ever yet been built to stand the racking of any motive power sufficiently strong to project her through the water (and especially troubled water), at the rate of 24 miles an hour. I do not say this will never be done, but builders and shipowners cannot afford to use up all the room in a ship for the sake of testing the maximum of speed to be got out of the same. As vessels are increased in length they cannot in the same proportion be increased in width, because they would be so stiff and offer so much resistance to a cross sea. The motion would be so sharp and quick, that nothing could be kept in place, and the poor unfortunates on board would be thrown off their legs, and wrenched away from anything they might lay hold of, or be bruised to death by a motion in the opposite direction.—WM. HOSKEN.

[52728.]—**Deposit in Water Cistern.**—Obviously, the "red spotted rust" is iron; but exactly whence it cometh would require a little examination to determine. Most likely the cistern is imperfectly coated with the zinc—that is, there are pinholes in the covering, and through these the iron is rusted, the action being assisted by the fact that the iron and zinc make a voltaic couple. If so, the cistern won't last so long as it would have done without the zinc plating.—WATERMAN.

[52729.]—**Bronzing Mounts.**—This can be done by means of Bessemer's paint; or by brushing over gold size, printers' or other suitable varnish, and then dusting the powder over, wiping when dry and fixed with a tuft of cotton wool.—NUN. DOR.

[52730.]—**Legal.**—This question of "nuisance" is very much a matter of opinion. The law is clear enough: if it is a "nuisance," why then you will have to shift your engine; but a judge would require very strong evidence, or it would rest with a jury, according as the case is tried. Better take the advice of a respectable solicitor, who will examine the spot; but I think if the engine is 23 yards from a public way, and not near any houses, it would puzzle the other side to prove a "nuisance." —LIMB O' TH' LAW.

[52736.]—**Gelatine.**—This is a question to be settled by experiment. There must be gelatine in ham-rinds; but whether it is worth the trouble, or can be obtained, is another matter.—ECONOMY.

[52761.]—**Consumption.**—"Muse" asks a very important question, and one of vital importance, How to prevent chronic lung complaints from turning to consumption, or how to cure consumption in its first stages? Such a consummation cannot be arrived at by drugs, but must be done by careful attention to hygienic and dietetic rules. In the first place, all lung complaints mean a deficiency of fresh air; in the second place, they are aggravated by foods which require much oxygen for their oxidation (as flesh foods), and they are also made worse by lowering conditions of any kind. If "Muse" wants really to get rid of his complaint, he must change his occupation for one in which he is more in the open air; or, if he cannot do that, he must make it a rule to be out in the open air as much as possible, and even sleep with his bedroom window a little open. Secondly, he must adopt a diet which will digest very easily, and not supply his system with too much waste material. A non-flesh diet will best supply him with nourishing food not too rich in waste products. For breakfast, he can have a porridge made from an equal mixture of oatmeal and wheatmeal; a basin of this, eaten with milk (as he is losing flesh, he might mix a tablespoonful of olive oil with it), if well mixed, he will not taste it, and it will not repeat. Let this suffice for the first meal. Dinner, five hours after, may consist of a plain soup and brown bread, followed by a rice, sago, tapioca, or hominy pudding, made with milk only and a very little sugar. Tea meal, five hours after dinner, may consist of weak tea, coffee, or cocoa, or hot milk, for drink, with wholemeal bread and butter. Let this be his last meal. In chest cases, the stomach always sympathises with the lungs, and so the patient loses weight by not being able to digest the food. Again, flesh food often gives rise to pain in these cases, or brings on an attack of coughing, which ceases not until the offending food is vomited. When we know that the lungs and stomach are supplied by the same nerve (pneumo-gastric) we see the cause of it, for anything irritating the stomach end of the nerve gives rise to coughing, which may induce vomiting, and thus relief is got. Again, flesh food often gives rise to night sweats, which are, I believe, an effort of the system to relieve itself from waste products. These sweats are very weakening, though. Thirdly, he must attend to his skin, and keep it open, for the lungs and skin are both blood purifiers, and when the lungs are disabled we must try and make the skin do some of their work. This can best be done by means of daily tepid baths, or sponging the whole body with lukewarm water once or twice daily, to be followed up by a brisk rubbing down with a rough towel. If "Muse" will try and follow these rules I will promise him cure. These rules are also very useful for the first stage of consumption, and if properly carried out, will save many from an untimely grave. Consumption in its early stages can be cured, and even in its more advanced stages much relief may be got from following simple hygienic and dietetic rules. If my professional brethren would use more hygienic rules, and less physic, consumption would not be reckoned so fatal a malady as it is.—T. R. ALLINSON, L.R.C.P., 34, Claremont-square, N.

[52767.]—**Lathe Bearings.**—This querist should look up his back numbers. The wear is taken up by a turn or part of a turn of a nut, driving the mandrel further in.—T. G.

[52796.]—**Income Tax.**—I don't think you can be charged, if the property pays all taxes in New Zealand; but clearly if anyone resident in this country derived his income from property abroad he would have to pay the tax.—S. T. J.

[52824.]—**Governors.**—The small balls have the advantage of not wearing the suspension pin guide, pins, footstep, &c., so much as the large balls do. But it is the length of the arm and the angle it makes with the vertical shaft, or the distance from point of suspension to plane of revolution by which the action of a governor is regulated.—ENGINEER, Dewsbury.

[52840.]—**Core Box for Globe Valve.**—As you are a pattern-maker, I need scarcely allude to the pattern itself for a globe valve, except in so far as it may be useful to others. It might be jointed in the plane of Fig. 1 (vertical section), and be either worked out of a solid piece, if of small dimensions; or if large, the globular part would be turned together with the inlet and outlet ends and their prints—the branch for the screw gland being turned separately and fitted on. Or the pattern might be jointed at right angles to the plane of Fig. 1—that is, vertically—and the branch be moulded downwards: and this I consider the better way, as more convenient for laying in the cores. A small valve has usually nut-shaped ends as figured, and screwed within with gas-taps for the attachment of the piping. But large valves have often flange attachments, both at the ends and on the top, and in the latter case the top flange will be left loose, if the branch is moulded downwards. But the core is the thing, and that is not made in one, but in two. Form two separate boxes, and fasten together with claywash before being put into the mould. Looking at Fig. 1, A is one core and B is the other, and they are connected together by the prints shown dotted in the figure. In setting to work, just dismiss core B from the mind for awhile, and start about making a box for A. I have shown three views of the box (Fig. 2), A showing the appearance of the box viewed from its outer end; B, in sectional plan, looking on the face of the core box joint and downwards; C, a sectional elevation cut longitudinally through the box. The necessary lines of course you know how to mark from your drawings. You can see now clearly that the box

ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

A NEW VOLUME.

This number is the last of Vol. XXXVIII. Readers willing to oblige us by recommending "ours" to new subscribers should do so now, when a new volume is commencing. The index to Vol. XXXVIII. will be published on March 21, and cases and bound volumes will be on sale shortly after. Readers desirous of making up their sets for binding the present volume are recommended to do so at once, as the back numbers soon run out of print.

The following are the initials, &c., of letters to hand up to Wednesday evening, Feb. 27, and unacknowledged elsewhere:—

J. H. Cussen.—J. and H. Grace.—W. F. Stanley.—Leroy and Co.—T. Taylor.—Mawson and Swann.—J. Wimshurst.—G. W. Weeks.—Arthur Henry.—J. Reside.—R. Hughes.—H. King.—J. H.—Expertus.—W. H. Baldwin.—O. V.—T. W. Smith.—W. Shield.—Moongazer.—George Templeton.—F. P.—P. E.—Coppersmith.—G. R.—Economist.—Enquirer.

J. Lawrence. (Perpetual motion is the thing for you! That is the only way we know of getting a machine to go twenty-seven hours a day, eight days a week, all the year round, and this really seems what you want.)—B. S. L. (Natural flowers may be preserved by taking them when fresh cut and dipping them in paraffin melted enough to maintain its fluidity. Move the flowers about very carefully in the liquid so as to remove all air bubbles; withdraw quickly and hold a moment to dry.)—Table Decoration. (Here is one way by which you may florally designate places at table for your guests, if you have plenty of violets or other small blooms to spare: Have an alphabet made of tin, have each letter about three inches high and the little tin forms deep enough to hold a little sand or wet moss. Then fill the forms with tiny flowers and leaves.)—Demagnetised. (The query has been answered over and over again, and directions are given in nearly every textbook. A great deal depends on the nature of the steel; but it is usual to magnetise either by drawing a permanent magnet in one direction over the bar, or to use a coil of wire through which a current is passing, and lead that along the bar it is desired to magnetise. You do not state the shape, whether bar or horseshoe.)—A Sufferer. (It is impossible to learn from your reply even the nature of the rheumatism, whether it proceeds from rheumatic gout or from the acute or chronic form. See p. 154, Vol. XXXV., and the indices generally.)—Mechanic. (Rub soap over the part, scratch the lines with a needle, and then fill them with nitric acid, the aquafortis of the shops.)—Horatius. (See Dr. Stone's note on p. 5, Vol. XXXVII., or Dr. Edmunds's, p. 430, Vol. XXXV.)—Sportsman. (Canvas-back 'ducks are specimens of the *Aythya vallisneria*. They reach the United States from the north in October and about November are in prime condition. Caught largely in Chesapeake Bay.)—H. A. (Either the glass is not clean or the plaster has perished. Procure the best plaster, and see that the glass is thoroughly clean. About the consistency of paste. If the plaster is fresh and good, it practically burns into the surface of the glass and cannot easily be removed.)—Inquirer. (See the indices, or consult the lists of those who sell hot-water fittings. The boiler would be placed at the back of the grate; but it really requires examination of the place to determine what would be best arrangement.)—Cyclist. (We suppose you mean the Wealemefna; but the names of the instruments are the opisometer and the chartometer—sold by all dealers in drawing instruments, such as Stanley.)—Eachin. (The remedy is to paint the tins and stick the labels on that.)—Amateur. (See the indices, and pp. 242, 303, 368, present volume.)—W. H. W. (See p. 441, Vol. XXXV. There are several things of the kind; but it is doubtful whether they are worth anything.)—Ignorance. (Apparently it wants cleaning out; but your description is very vague. Do not understand what you mean by a waste.)—D. T. (See any textbook of chemistry, or dissolve it in sulphuric acid.)—Animalcula. (Prof. Westwood, of Oxford, read a paper on the subject at the 1879 meeting of the British Association, an abstract of which you will find in Vol. XXX., p. 81. If you could catch some of the depredators and send them to Prof. Westwood he would identify them for you and indicate a remedy. Russia leather is said to be proof against them, and as that derives its peculiar scent from oil of birch, you might try the effect of that in your bookcases. You will find several remedies suggested in P of. Westwood's paper.)—Self-Taught. (They are merely examination questions, for which at present we have not space.)—H. W. H. (See the indices. The only satisfactory method is exposure to bright sunshine under the protection of glass.)—Try. (See the list of Back Numbers at the head of this column first week in each month. Copying Processes is the heading.) X. N. X. (It was omitted at the last moment, owing to the exigencies of printing. With some others it was in type, but had to be held over.)—E. J. C. (The recipes appeared under the head "Moire Metal," in Vol. XXXVII. p. 320.)—Pip. (Have you read what has appeared on the subject. See p. 226, Vol. XXXVII., and the indices generally.)—T. S. P. (You will probably find good Brunswick black as serviceable as anything; but some prefer to blacklead. Coal-tar well boiled and diluted with turpentine and boiled oil is a good paint for such purposes.)—Gunner. (See p. 605, Vol. XXIX. All that is needed is a chamber, into which air is pumped at a high pressure; the trigger opens a valve in this and the air escaping drives the bullet or dart out of the barrel.)—E. C. Alcock. (The registration of a trade mark costs 5s. for the stamp on application, and a pound before the expiration of every fourteen years.)—P. C. W. (You could try Brunswick black or Japan varnish; but surely porcelain or guttapercha is cheap enough.)—Gamma Alpha Sigma. (See the indices, for something has been said that may be of use; but you should procure the handbooks issued by Gordon and Gotch, St. Bride-street, or seek advice from the Agent-General to the Colony to which you wish to emigrate.)—Adam. (Do you not see that such a query would bring replies which would be advertisements, although they might not be meant as such.)—G. R. K. (It does not matter. For convenience it is generally placed at the end where the primary wire commences. Very shortly now, we believe; but ask Messrs. Spon.)—Organ Repairer. Whatever do you mean? What sort of an organ is it, and which G sharp?)—Brento. (Impossible to say without seeing it. The spring ought to be strong enough to pull it back. Perhaps contact is not broken—that is, the battery circuit—and the core acts as an electro-magnet.)—A Duffer. (Not without apparatus quite as complicated. The wires should be marked. 2. A motor of the kind was described on p. 113, this volume. 3. Apply to the Secretary, South Kensington. There are special regulations for persons residing where there are no classes.)—A Lancashire Lad. (You want an ordinary inside tool. Surely you have one of the handbooks which explain those matters.)—Grocer. (Boil a weighed quantity in water. Allow it to settle and cool, and then weigh. That is a rough test of the addition of adulterants.)—Lowlander. (It is not in the list. We know nothing about it. 2. Not yet. The brake pipes are disconnected at the previous station, and the carriages slipped by the link illustrated on p. 319, Vol. XXXVII. The trains on the L. and N.W. were given recently we think. We know of no other book of a descriptive kind.)—Saxon. (Apply to the Secretary of the Institute, 3, Copthall-buildings, E.C., or see p. 307, Vol. XXXII.)—Emigrant. (Procure the lists of Lockwood and Co., Stationers' Hall-court, E.C., and Spons, Charing-cross.)—Young Enquirer. (Is not the matter treated in "Notes on Plumbing"? The best joints are made with flanges and rubber rings. Handbook on the subject frequently advertised in "Sale Column," See p. vi., Feb. 8, for instance.)—Phœnix. (We have inserted many similar diagrams, and the replies will supply all the information needed. See the index of the last volume.)—W. F. Gardiner. (Just the same as other insects are preserved. 2. The area included between Chingford, High Beech, Epping, and Loughton would appear to be the best hunting-ground.)—Learner. (See p. 476, and the indices generally. 2. An answer would occupy too much space; it must be looked for in the official instructions or in works on meteorology. 3. Examining the water, and comparing its analysis with the rate of flow.)—W. Clark. (When you write again about something you do not understand, it would be advisable at least to spell correctly, and arrange the words in grammatical form. What do you know about "the nervo-vital fluid," or of the cause of the "viger and activity witch wee witness in the young"?)—E. T. (Have no space for queries about banjoes made out of cocoanut shells. You must experiment for yourself; perhaps you may make a discovery.)—W. H. Hall. (The method has been described over and over again, and recently. If the articles are not sufficient guide, you must wait. We cannot afford space to give measurements and details of every size asked about, though all the size you mention is the highly definite description "small one.")—Forward. (Your five questions are answered by the simple statement that there is not an examination of the kind. Anyone can put C.E. after his name.)—Frugal. (We should say any man just now who placed money in an "Advance and Deposit Bank" on a guarantee of ten per cent. interest would lose his money.)—David Smart. (We cannot reproduce the sketches satisfactorily, best thanks all the same.)—An Ignorant One. (You must take out a license if you sell certain articles—such as sweets, tobacco, wines, &c.)—W. C. S. (He will have to pay it, or prove to the satisfaction of the Commissioners that he is losing as you say.)—Gibraltar. (We doubt if such an invention would ever pay the costs of the patent. Any of the agents advertising in these columns will answer your other questions.)—A. Robinson. (Do not listen to croakers, but take medical advice. The people who "have got worse instead of better," would probably have got worse still if they had neglected the matter.)—R. H. Bleasdale. (You have your remedy if the case is as you say. We cannot exclude advertisements on such representations. If we did we should have to assume a similar responsibility in all cases.)—Bridgwater. (Your father's marriage will invalidate any previously made will, and should he die intestate you and the other children of either marriage will share his personal property equally.)—Schiox. (Why not look for yourself? Try No. 986.)—W. J. Goldsmith. (Do you not think it rather absurd to send such a cutting to us? See the indices of back volumes, and pp. 121, 362, 368, 393, 431, 471, 473 of the present volume.)—Multipot. (The best way is to use a cupola, which you will find described in back volumes.)—J. W. or X. A. B. (The book you mean was advertised on p. xi. of the number for Feb. 15.)—B. (The necessary recipes will be found in the back volumes; but you will probably find the aniline dyes sufficient for your wants.)—M. E. C. (We have heard that the essence of pennyroyal, or fresh sprigs of the plant, scattered about the room will drive them away.)—Luke. (See the indices and recent back numbers.)—Thomas Plunkett. (Not on the small scale; but you do not want illuminating gas for the purpose. See p. 154, Vol. XXXII., and the indices. Also p. 527, last week's number.)—Samuel Smith. (All the information necessary was given on p. 431, Vol. XXXVII. You never will make them soft until you work them well, instead of allowing them to become dry and hard.)—Inquirer. (Three ounces of shellac, half-ounce of benzoin, to a quart of rectified wood naphtha, make a good polish. For directions, see many back numbers; but full instructions will be found in Vol. XXXII., pp. 175, 227.)—Confectioner. (You mean a pyrometer; write W. H. Bailey and Co., of Salford, for prices, &c.)—Carnivorous. (It is very much a question of temperature. Tough meat, and generally speaking, the flesh of wild or undomesticated animals is better hung as long as possible before being cooked. Fresh venison, for instance, is decidedly unpalatable, and—we write in wholesome fear of vegetarians and others—we think unwholesome. Given bright, clear, cool weather, like that we are enjoying as we write this, and a leg of mutton may safely hang a fortnight, and taste all the better for it; while in hot summer weather it would stink before the first week was over.)

Every Workman connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 31, Tavistock-street, Covent-garden, London, W.C.

"THE BUILDING NEWS" is the Principal Journal, representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 1d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 1d. each copy, to cover extra postage.

Vols. XXIV., XXVII., XXVIII., XXX., XXXI., XXXII., XXXIII., XXXIV., XXXV., XXXVI., and XXXVII., bound in cloth, 7s. each. Post free, 7s. 9d.

[Vol. XXXVIII. Ready Shortly.]

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

CHARGES FOR ADVERTISING.

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

	s.	d.
Sixteen words	0	6
For every succeeding Eight Words	0	6

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

Throat Irritation and Cough.—Soreness and dryness, tickling and irritation, inducing cough, and affecting the voice. For these symptoms use Epps's Glycerine Jujubes. In contact with the glands at the moment they are excited by the act of sucking, the Glycerine in these agreeable confections becomes actively healing. Sold only in boxes 7½d., tins 1s. 1½d., labelled "James Epps and Co., Homœopathic Chemists, London." A letter received: "Gentlemen,—It may, perhaps, interest you to know that, after an extended trial, I have found your Glycerine Jujubes of considerable benefit (with or without medical treatment) in almost all forms of throat disease. They soften and clear the voice.—Yours, Gordon Holmes, M.D., Senior Physician to the Municipal Throat and Ear Infirmary."

Holloway's Pills have many competitors, though no equals, for supplying the young and delicate with a simple, strengthening, and purifying aperient. These Pills, composed of the finest balsams, are particularly adapted for all complaints peculiar to females, and are most serviceable at the critical periods of early and mature years.

OUR EXCHANGE COLUMN.

The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.

Declining Business.—Forty English Lever **Watches**, a few Chronographs. List free. Offers requested in part exchange. —R. Powall, Prescot, Lancashire.

Wanted, **Ironing Stove**, flat top, 10in. square, piping, for splendid high-class copper and plaster medallions, or Fletcher's foot blower.—Ward, Woodlands Park-road, Greenwich.

Exchange for Tricycle **Two No. 1 Thomas's** Sewing Machines without treadles, warranted in good working order.—E. T. Baker, East-street, Ilminster.

Wanted, **Iron Printing Press**, to print 12in. by 16in., with or without type, will give in exchange chassepot breechloader and sword worth 30s. and cash, or part exchange in jewellery and cash for good article.—E. Wilton Newton, Camborne, Cornwall.

Telephones, a short time in use.—Pair of complete simplex telephones, each instrument has Strangways' microphone, bell, switch automatic and ear-tube receiver; exchange Fletcher's furnace, blower, tubing, and generator, or value £4.—T. Plunkett, Portmarnock, Baldoyle.

Electric Machine, 10in. by 6in. cylinder; London only, particulars free. Exchange for Lancaster's Instantograph, ½-plate.—C. Parker, 15, Osborne-grove, Upper Tollington-park, N.

Electro-Plating.—Gallon Smee, good order; lot of steel and agate burnishers; exchange clothing.—G. E., 25, Chandelier-road, Stratford, London, E.

A first-class 6in. centre **Lathe**, with back-gear, slide-rest and chucks, 5ft. 6in. bed, too large for owner, who wants one about 4½ and much lighter.—Levi, 120, Hammersmith-road, W.

Lancaster's half-plate **Lens**, stand, and double back; also home-made camera, in exchange for scientific apparatus, or offers.—A. Chambers, 6, Gordon road, West-hill, Hastings.

Wanted, **Tricycles**, single or sociable; condition immaterial; give in exchange bicycles in perfect condition, new if desired; good value may be relied upon.—W., 59, Maxey-road, Plumstead.

Wanted, anything useful to engineer in exhange for 50in. Singer bicycle, perfect condition.—W., 59, Maxey-road, Plumstead.

What Offers in exchange for Stanley's best quarter-plate lens, camera and stand, equal to new.—Grimshaw, Dale-street, Haslingden.

Winter Machine. Coil, Motor (electro) for vacuum tubes, two pint bichromates, and dissecting microscope, lot worth £6 10s. Wanted astro. telescope or binocular microscope, cash for difference if any.—A. Thomson, 27, Paterson-street, S S., Glasgow.

Four Acorn **Incandescent Lamp Holders** (Edison's), cost 16s., model vertical engine, 1in. stroke, cost 10s. 6d., for 4lb about No. 25 c.c. wire.—12, Renfrew-road, Lower Kennington-lane, London, S.E.

Organ Scundboard for 5 stops, with pallets and springs, offers in exchange.—B. Martin, Overton-road, New Humberstone, Leicester.

Handkerchiefs.—Two dozen very fine Cambric lady's size in two handsome folding cartoons; exchange anything useful to 20s. value.—Joseph Knox, Needwood-terrace, Belfast.

"**Engineering,**" 40 recent numbers, and English Mechanic, 3 years in monthly parts for binding; also 120 weekly Nos., for lathe or useful exchange.—Fisher, Marchant-villa, Ponders-end, London, N.

Photographic Materials, Telescope, Gas Regulator, to exchange for lathe, back geared.—George Neal, High-street, Chesham.

"**Astrology**" (William Lilly), published 1647. Exchange for something photographic.—Astro., 279, Great College-street, Camden Town, London N.W.

Half H.-P. horizontal **Engine**, quite new, value £5. Wanted Griscom's or Cuttriss electric motor and battery, or medical coil.—T. Carter, 12, Park-street, Stafford.

Superior **Beam Engine**, with governors and pump, very strong and well made, value £6 10s.; wanted American organette or tricycle, approval.—Address above.

Half H.-P. horizontal **Engine**, in working order, value £4. wanted Anglo German concertina, on approval, no rubbish, in lock-up box.—Address above.

Patent **Lathe and Fret Saw**, by Britannia Company, cost £5 17s. 6d. good condition, what offers in exchange?—T., 14, King-street, Reading.

Organette, with 13 pieces of music. Exchange for 46in. bicycle in good condition.—Apply George Elas, 274, Alfred-street, Central, Nottingham.

Exchange "**Cassell's Popular Educator**," excellent condition, for 26in. Gladstone bag, perfect; waterproof coat wanted to fit man 5½ft., good exchange.—13, Bridgwater-square, Barbican, E C.

Good silver English **Lever**, by Benson, cost £6 6s., perfect timist; exchange for lathe, or what offers.—Frank Goby, Bull-road, Colchester.

Medical Coil and Battery, in case, very powerful, cost £3; will exchange for bicycle fittings, or offers.—George Andrews, Tinner, Knaresborough.

"**English Mechanic**," unbound, Vols. XII., XIII., XIV., XV., XVI., XXII., XXVIII., XXIX., XXX., XXXI., XXXII., exchange for bichromate bottle battery, quart size.—Mr. Garside, 17, Strawberry-hill, Pendleton, Manchester.
